

NORSAR Scientific Report No. 1-93/94

# **Semiannual Technical Summary**

1 April — 30 September 1993

Kjeller, November 1993

APPROVED FOR PUBLIC RELEASE, DISTRIBUTION UNLIMITED

# **7.2** The Lop Nor nuclear explosion of 5 October 1993

# Introduction

As described in Section 7.1, we conducted a threshold monitoring experiment for the Lop Nor test site in Southern Sinkiang, China, for several days prior to the 5 October nuclear explosion. A large earthquake and aftershock sequence occurred in the Southern Sinkiang province only three days before the explosion, and this gave an opportunity to make some interesting comparisons, elaborated upon in this study.

### The Lop Nor nuclear explosion of 5 October 1993

The explosion took place on 5 October 1993, with origin time 02.00 GMT. Table 7.2.1 lists the basic parameters of the event as provided by various sources. The  $m_b$  magnitudes range from 5.65 to 5.90. The most accurate location is provided by the PDE bulletin, which uses a world-wide network for location purposes. The solutions by the Intelligent Monitoring System (IMS) (Bache et al, 1993), both automatic (IMS) and after analyst processing (ARS), are also listed. The NORSAR automatic and reprocessed solutions (based on the new SUN-based processing system) are included in the table. The SUN-based NORSAR trace plot is shown in Fig. 7.2.1.

Figs. 7.2.2 and 7.2.3 show plots of the interactive IMS processing results. The trace plots of Fig. 7.2.3 are based on array beams for the four arrays Apatity, ARCESS, NORESS, GERESS and a single channel (A0) for Spitsbergen. The FINESS array was not yet operational at the time of the explosion.

Table 7.2.2 summarizes the automatic processing results for the six arrays. The NORESS array has the best signal-to-noise ratio (1376.2) for this event, and by extrapolation this array would be expected to have a detectable signal for an event about 2.5 magnitude units lower. ARCESS and NORSAR also show outstanding SNR. The velocity/azimuth estimates are within the expected uncertainty for all arrays. Note that the Spitsbergen array is only partially installed, and this is reflected in its processing results.

#### Comparison with previous events

We now proceed to make a brief comparison between the 5 October 1993 explosion, the large 21 May 1992 explosion at the same site and the two largests events in the 2 October S. Sinkiang earthquake sequence.

Table 7.2.3 summarizes the PDE parameters for these four events. The 21 May 1992 explosion is comparable in  $m_b$  to the main shock of 2 October 1993, and the 5 October 1993 explosion is comparable to the 2 October 1993 aftershock. This similarity is illustrated by Fig. 7.2.3, which shows the NORESS P-wave recordings (A0Z seismometer) for the four events, all plotted to the same scale.

Fig. 7.2.4 show long-period recordings, from the NORESS broad-band seismometers for the four events. Again, the same scale is used in all four cases. The surface waves of the

main earthquake have been "clipped" (for display purposes). This figure is very illustrative, and the following observations may be made.

- As expected, the main earthquake and the large May 1992 explosion have vastly different size of surface waves, in spite of their similar  $m_b$  value. Thus, discrimination based on  $M_s:m_b$  is simple in these cases.
- The October 1993 Lop Nor explosion can likewise be readily identified as an explosion on the basis of  $M_s:m_b$  at NORESS, either by measuring  $M_s$  on the "marginal" surface wave shown on Fig. 7.2.4, or by using "negative evidence" in the case of NORESS. In fact, the long-period "noise magnitude" is well below the expected  $M_s$  value for any earthquake of corresponding  $m_b$  value.
- The surface waves of the 2 October aftershock cannot be measured on NORESS recordings, and this event cannot be identified as an earthquake from NORESS data using M<sub>s</sub>:m<sub>b</sub>. The reason is the large coda level even one full hour after the main shock.

It has previously been found, on the basis of the GSETT-2 experiment (see section 7.6) that a modern network dominated by high-frequency arrays is very efficient in detecting aftershocks closely following large earthquakes (see also Ringdal, 1992). The reason is that the high-frequency coda drops very rapidly after the initial P onset, and the high-frequency arrays are able to exploit this drop-off in the detection processing. On the other hand, the long-period coda stays at a high level for many hours following large earthquakes, and no efficient methods have been found so far to suppress this coda sufficiently to extract very small surface waves. This is only one of many examples illustrating that the progress in recent years in seismic event detection has not been matched by a similar progress in event identification.
