# Semiannual Technical Summary 

1 April - 30 September 1995

Kjeller, November 1995

NORSAR Scientific Report No. 1-95/96

# Semiannual Technical Summary 

1 April - 30 September 1995

Kjeller, November 1995

#### Abstract

(cont.) The NORSAR Detection Processing system has been operated throughout the period April August 1995 with an average uptime of $99.1 \%$ as compared to $99.6 \%$ for the previous six-month period. During September 1995, the NORSAR array was out of continuous operation due to the final refurbishment effort. Backup during this period was provided by the NORESS array, colocated with NORSAR subarray 06C. NORESS continued to be in full operation during the refurbishment work. A total of 2027 seismic events have been reported in the NORSAR monthly seismic bulletin for April - August 1995. The performance of the continuous alarm system and the automatic bulletin transfer to AFTAC has been satisfactory. The system for direct retrieval of NORSAR waveform data through an X. 25 connection has been used successfully for acquiring such data by AFTAC. Processing of requests for full NORSAR and regional array data on magnetic tapes has progressed according to established schedules.

This Semiannual Report also presents statistics from operation of the Intelligent Monitoring System (IMS). The IMS has been operated in a limited capacity, with continuous automatic detection and location and with analyst review of selected events of interest for GSETT-3. Data sources for the IMS have comprised all the regional arrays processed at NORSAR.

Since 1 October 1991, an effort has been undertaken to carry out a complete technical refurbishment of the NORSAR array. This project is funded jointly by AFTAC, ARPA and NFR. During the reporting period, work continued on gradually installing new digitizers, communications modules, broad-band seismometers of the KS-54000 "posthole" type as well as new short-period seismometers of type Teledyne Geotech S-20171. As of November 1995, the refurbishment effort was completed.

On-line detection processing and data recording at the NORSAR Data Processing Center (NDPC) of NORESS, ARCESS, FINESS and GERESS data have been conducted throughout the period. Data from two experimental small-aperture arrays at sites in Spitsbergen and Apatity, Kola Peninsula, as well as the Hagfors array in Sweden, have also been recorded and processed. Monthly processing statistics for the arrays as well as results of the IMS analysis for the reporting period are given.

Maintenance activities in the period comprise preventive/corrective maintenance in connection with all the NORSAR subarrays, NORESS and ARCESS. Other activities have involved testing of the NORSAR communications systems, preparations for the NORSAR refurbishment and work in connection with the experimental small-aperture arrays in Spitsbergen and Russia.

Summaries of seven scientific contributions are presented in Chapter 7 of this report.
Section 7.1 is a paper entitled "Analysis of data recorded at the Spitsbergen array". This paper presents results from analysis of data recorded at the Spitsbergen array (SPITS) from events in the Svalbard region during the period July through December 1994. Through this period 1258 seismic events in the Svalbard region were manually checked and located using data from the SPITS array. The broad band capability of the new extended short-period Guralp sensors installed August 1994 is demonstrated through records of the Chinese nuclear test on 7 October 1994 and is further illustrated by SPITS recordings from two events on the Knipovitch Ridge and SE Spitsbergen. These latter two events occurred before and after the sensors were changed, and the difference in data quality is evident. The new Guralp extended short-period sensors provide resolution also of the lower frequencies, where the larger earthquakes are particularly rich in energy. The smaller nearby
earthquakes do not have sufficient low frequent energy to exceed the background noise, and hence must be filtered before the signal can be recognized.

Section 7.2 presents a comparison of the NORSAR array monthly bulletin with the Reviewed Event Bulletin (REB) of the GSETT-3 IDC. The paper lists 207 seismic events detected and located by NORSAR, but not reported in the REB during January-August 1995. Most of these events are clustered in four areas: the Balkans, Hindu Kush, Japan and the Kuriles, and the Fiji-Tonga-Kermadec area. Taking into account the uncertainty in the magnitude estimates, it is concluded that this investigation has qualitatively confirmed the theoretical detection thresholds of the GSETT-3 network in the four regions considered. Also, it shows that introduction of the NORSAR teleseismic array in the GSETT-3 primary network in the near future holds promise that more events from these four regions will enter the REB. In this connection, it is noted that the on-going implementation of an improved NORSAR detector algorithm might add further events from areas where the NORSAR array is especially sensitive.

Section 7.3 is a paper entitled "Development of improved NORSAR time delay corrections". The paper briefly reviews the development of the large NORSAR array, which initially comprised a configuration of 22 subarrays distributed over a diameter of 100 km . After six years of experimental operation, the array was modified on 1 October 1976 to a reduced configuration which was more suitable for an automated, operational system, and the 7 best subarrays (in the NE part of the original array) were selected for this purpose. This configuration is still in operation today, with each subarray comprising 6 SP and one 3 -component BB seismometer over an area 8 km in diameter. The total aperture of NORSAR is now 60 km . This array configuration enables excellent teleseismic detectability and location capability. A complete technical refurbishment of the NORSAR array is now being finalized.

In order to take full advantage of the NORSAR capabilities, it is desirable to update the beam deployment and revise the time delay anomalies taking into account the improved precision made possible from the increased sampling rate ( 40 Hz against previously 20 Hz ) and the accumulated data base of reference events. This paper gives a progress report on the work carried out until now, and comprises an initial data base of 55 reference events. This data base will be further expanded in the future.

Section 7.4 is a paper entitled "Automatic onset time estimation based on autoregressive processing". This study has been undertaken in order to support the developments at the GSETT-3 IDC, and is based on the use of an autoregressive method for automatic onset time estimation, denoted AR-AIC. This method has for several years been operational in the processing of data from the Japanese national seismic network, and the software has been provided to us by scientists from the Japanese NDC.

In this paper we have adapted the Japanese method for application to GSETT-3 data, with emphasis on developing an automated procedure that includes new features such as multiple narrow-band filters, the concept of "usable bandwidth" and a quality measure of the estimated onset time. It is demonstrated that the AR-AIC method for onset time estimation can be adapted to work on a wide range of seismic signals. In particular, the quality measure makes it possible to distinguish between reliable and unreliable onsets. In this way we can avoid using erroneous data in the event location procedure and thus improve the location precision of the automatic processing system.

Section 7.5 is a paper entitled "Recommendation on Auxiliary Seismic Stations for the IMS Network". This contribution is a lightly edited version of a paper prepared by the GSETT-3 Working Group on Planning (WGP) in preparation for the 42nd GSE session in Geneva during 27 Novem-
ber - 1 December 1995. The main purpose of this GSE meeting was to make a specific recommendation for the auxiliary seismic network of the International Monitoring System (IMS), which will be installed to verify compliance with a Comprehensive Test Ban Treaty.

The paper provides the preliminary recommendation from the WGP and is intended as a basis for discussions during the 42nd GSE session. The network designs proposed herein will be reviewed and revised during the GSE session as additional information is received from GSE participants. Material on relevant experience from GSETT-3 will also be taken into account in the process of selecting a recommended IMS auxiliary network.

It is noted that further work and discussion are needed to establish the exact location capability of the networks and the operational status for the existing auxiliary stations proposed in this paper, and to check the progress of plans and proposals for the stations that are not yet operational. Further work is also needed to estimate the costs related to bringing stations and communications arrangements in line with the required IMS standards.

Section 7.6 contains a case study of magnitude estimation at the IDC. The paper contains a detailed analysis of a recent earthquake sequence in Greece during May-June 1995. This includes comparisons of IDC magnitudes in the Revised Event Bulletins to those of NORSAR and NEIC, with special view to network bias, recurrence statistics and detectability.

The paper demonstrates that the IDC $m_{b}$ values are subject to the same "network bias" as the NEIC magnitudes for small events. This implies that the recurrence plots (magnitude/frequency) of IDC data have a too steep slope, which again might lead to a significant overestimation of the number of earthquakes expected to be processed at the IDC. The paper confirms the validity of the theoretical $90 \%$ detectability estimate of the GSETT-3 system presented in the IDC performance reports. This estimate is currently close to $\mathrm{m}_{\mathrm{b}}=4.2$ for the area analyzed.

Section 7.7 contains an assessment of the estimated mean mislocation vectors for small-aperture arrays. The objective of this study has been to test the applicability of the estimated mean mislocation vectors for small-aperture arrays for use with different event-location procedures. The mean mislocation vectors were calculated in the slowness space and are now available for automatically estimated fk-results over a large range of azimuth and ray-parameter values. Additionally, mean standard deviations for the mislocation vectors could be defined as a function of the measured slowness values. All this information can now be used to increase the stability and quality of both phase association and event location based on automatically estimated fk-results.

Location results before and after the application of slowness and azimuth corrections are presented for about 25,000 events located during 1994 by ARCESS, FINESS, GERESS and NORESS. Furthermore, single-array solutions during 1995 are compared to REB-reported events both before and after applying the slowness corrections. The study concludes that the corrected slowness vectors provide a clear improvement and should therefore be used in the data processing at the IDC.

## 1 Summary

This Semiannual Technical Summary describes the operation, maintenance and research activities at the Norwegian Seismic Array (NORSAR), the Norwegian Regional Seismic Array (NORESS), the Arctic Regional Seismic Array (ARCESS) and the experimental Spitsbergen regional array for the period 1 April - 30 September 1995. Statistics are also presented for additional seismic stations, which through cooperative agreements with institutions in the host countries provide continuous data to the NORSAR Data Processing Center (NPDC). These stations comprise the Finnish Experimental Seismic Array (FINESS), the German Experimental Seismic Array (GERESS), the Hagfors array in Sweden and an experimental regional seismic array in Apatity, Russia.

The NORSAR Detection Processing system has been operated throughout the period April August 1995 with an average uptime of $99.1 \%$ as compared to $99.6 \%$ for the previous sixmonth period. During September 1995, the NORSAR array was out of continuous operation due to the final refurbishment effort. Backup during this period was provided by the NORESS array, co-located with NORSAR subarray 06C. NORESS continued to be in full operation during the refurbishment work. A total of 2027 seismic events have been reported in the NORSAR monthly seismic bulletin for April - August 1995. The performance of the continuous alarm system and the automatic bulletin transfer to AFTAC has been satisfactory. The system for direct retrieval of NORSAR waveform data through an X. 25 connection has been used successfully for acquiring such data by AFTAC. Processing of requests for full NORSAR and regional array data on magnetic tapes has progressed according to established schedules.

This Semiannual Report also presents statistics from operation of the Intelligent Monitoring System (IMS). The IMS has been operated in a limited capacity, with continuous automatic detection and location and with analyst review of selected events of interest for GSETT-3. Data sources for the IMS have comprised all the regional arrays processed at NORSAR.

Since 1 October 1991, an effort has been undertaken to carry out a complete technical refurbishment of the NORSAR array. This project is funded jointly by AFTAC, ARPA and NFR. During the reporting period, work continued on gradually installing new digitizers, communications modules, broad-band seismometers of the KS-54000 "posthole" type as well as new short-period seismometers of type Teledyne Geotech S-20171. As of November 1995, the refurbishment effort was completed.

On-line detection processing and data recording at the NORSAR Data Processing Center (NDPC) of NORESS, ARCESS, FINESS and GERESS data have been conducted throughout the period. Data from two experimental small-aperture arrays at sites in Spitsbergen and Apatity, Kola Peninsula, as well as the Hagfors array in Sweden, have also been recorded and processed. Monthly processing statistics for the arrays as well as results of the IMS analysis for the reporting period are given.

Maintenance activities in the period comprise preventive/corrective maintenance in connection with all the NORSAR subarrays, NORESS and ARCESS. Other activities have involved testing of the NORSAR communications systems, preparations for the NORSAR
refurbishment and work in connection with the experimental small-aperture arrays in Spitsbergen and Russia.

Summaries of seven scientific contributions are presented in Chapter 7 of this report.
Section 7.1 is a paper entitled "Analysis of data recorded at the Spitsbergen array". This paper presents results from analysis of data recorded at the Spitsbergen array (SPITS) from events in the Svalbard region during the period July through December 1994. Through this period 1258 seismic events in the Svalbard region were manually checked and located using data from the SPITS array. The broad band capability of the new extended short-period Guralp sensors installed August 1994 is demonstrated through records of the Chinese nuclear test on 7 October 1994 and is further illustrated by SPITS recordings from two events on the Knipovitch Ridge and SE Spitsbergen. These latter two events occurred before and after the sensors were changed, and the difference in data quality is evident. The new Guralp extended short-period sensors provide resolution also of the lower frequencies, where the larger earthquakes are particularly rich in energy. The smaller nearby earthquakes do not have sufficient low frequent energy to exceed the background noise, and hence must be filtered before the signal can be recognized.

Section 7.2 presents a comparison of the NORSAR array monthly bulletin with the Reviewed Event Bulletin (REB) of the GSETT-3 IDC. The paper lists 207 seismic events detected and located by NORSAR, but not reported in the REB during January-August 1995. Most of these events are clustered in four areas: the Balkans, Hindu Kush, Japan and the Kuriles, and the Fiji-Tonga-Kermadec area. Taking into account the uncertainty in the magnitude estimates, it is concluded that this investigation has qualitatively confirmed the theoretical detection thresholds of the GSETT-3 network in the four regions considered. Also, it shows that introduction of the NORSAR teleseismic array in the GSETT-3 primary network in the near future holds promise that more events from these four regions will enter the REB. In this connection, it is noted that the on-going implementation of an improved NORSAR detector algorithm might add further events from areas where the NORSAR array is especially sensitive.

Section 7.3 is a paper entitled "Development of improved NORSAR time delay corrections". The paper briefly reviews the development of the large NORSAR array, which initially comprised a configuration of 22 subarrays distributed over a diameter of 100 km . After six years of experimental operation, the array was modified on 1 October 1976 to a reduced configuration which was more suitable for an automated, operational system, and the 7 best subarrays (in the NE part of the original array) were selected for this purpose. This configuration is still in operation today, with each subarray comprising 6 SP and one 3 -component BB seismometer over an area 8 km in diameter. The total aperture of NORSAR is now 60 km . This array configuration enables excellent teleseismic detectability and location capability. A complete technical refurbishment of the NORSAR array is now being finalized.

In order to take full advantage of the NORSAR capabilities, it is desirable to update the beam deployment and revise the time delay anomalies taking into account the improved precision made possible from the increased sampling rate ( 40 Hz against previously 20 Hz ) and the accumulated data base of reference events. This paper gives a progress report on the work
carried out until now, and comprises an initial data base of 55 reference events. This data base will be further expanded in the future.

Section 7.4 is a paper entitled "Automatic onset time estimation based on autoregressive processing". This study has been undertaken in order to support the developments at the GSETT-3 IDC, and is based on the use of an autoregressive method for automatic onset time estimation, denoted AR-AIC. This method has for several years been operational in the processing of data from the Japanese national seismic network, and the software has been provided to us by scientists from the Japanese NDC.

In this paper we have adapted the Japanese method for application to GSETT-3 data, with emphasis on developing an automated procedure that includes new features such as multiple narrow-band filters, the concept of "usable bandwidth" and a quality measure of the estimated onset time. It is demonstrated that the AR-AIC method for onset time estimation can be adapted to work on a wide range of seismic signals. In particular, the quality measure makes it possible to distinguish between reliable and unreliable onsets. In this way we can avoid using erroneous data in the event location procedure and thus improve the location precision of the automatic processing system.

Section 7.5 is a paper entitled "Recommendation on Auxiliary Seismic Stations for the IMS Network". This contribution is a lightly edited version of a paper prepared by the GSETT-3 Working Group on Planning (WGP) in preparation for the 42nd GSE session in Geneva during 27 November - 1 December 1995. The main purpose of this GSE meeting was to make a specific recommendation for the auxiliary seismic network of the International Monitoring System (IMS), which will be installed to verify compliance with a Comprehensive Test Ban Treaty.

The paper provides the preliminary recommendation from the WGP and is intended as a basis for discussions during the 42nd GSE session. The network designs proposed herein will be reviewed and revised during the GSE session as additional information is received from GSE participants. Material on relevant experience from GSETT-3 will also be taken into account in the process of selecting a recommended IMS auxiliary network.

It is noted that further work and discussion are needed to establish the exact location capability of the networks and the operational status for the existing auxiliary stations proposed in this paper, and to check the progress of plans and proposals for the stations that are not yet operational. Further work is also needed to estimate the costs related to bringing stations and communications arrangements in line with the required IMS standards.

Section 7.6 contains a case study of magnitude estimation at the IDC. The paper contains a detailed analysis of a recent earthquake sequence in Greece during May-June 1995. This includes comparisons of IDC magnitudes in the Revised Event Bulletins to those of NORSAR and NEIC, with special view to network bias, recurrence statistics and detectability.

The paper demonstrates that the IDC $m_{b}$ values are subject to the same "network bias" as the NEIC magnitudes for small events. This implies that the recurrence plots (magnitude/ frequency) of IDC data have a too steep slope, which again might lead to a significant overestimation of the number of earthquakes expected to be processed at the IDC. The paper
confirms the validity of the theoretical $90 \%$ detectability estimate of the GSETT-3 system presented in the IDC performance reports. This estimate is currently close to $\mathrm{m}_{\mathrm{b}}=4.2$ for the area analyzed.

Section 7.7 contains an assessment of the estimated mean mislocation vectors for smallaperture arrays. The objective of this study has been to test the applicability of the estimated mean mislocation vectors for small-aperture arrays for use with different eventlocation procedures. The mean mislocation vectors were calculated in the slowness space and are now available for automatically estimated fk-results over a large range of azimuth and ray-parameter values. Additionally, mean standard deviations for the mislocation vectors could be defined as a function of the measured slowness values. All this information can now be used to increase the stability and quality of both phase association and event location based on automatically estimated fk-results.

Location results before and after the application of slowness and azimuth corrections are presented for about 25,000 events located during 1994 by ARCESS, FINESS, GERESS and NORESS. Furthermore, single-array solutions during 1995 are compared to REBreported events both before and after applying the slowness corrections. The study concludes that the corrected slowness vectors provide a clear improvement and should therefore be used in the data processing at the IDC.

## 2 NORSAR Operation

### 2.1 Detection Processor (DP) operation

There have been 2 breaks in the otherwise continuous operation of the NORSAR online system within the 5-month interval April through August 1995. The uptime percentage for this period is 99.1 as compared to 99.6 for the previous six-month interval.

During September 1995, the NORSAR array was out of continuous operation due to the final refurbishment effort. Backup during this period was provided by the NORESS array, co-located with NORSAR subarray 06C. NORESS continued to be in full operation during the refurbishment work.

Fig. 2.1.1 and the accompanying Table 2.1.1 both show the daily DP downtime for the days between 1 April and 30 September 1995. The monthly recording times and percentages are given in Table 2.1.2.

The breaks can be grouped as follows:

| a) | Hardware failure | 0 |
| :--- | :--- | :--- |
| b) | Stops related to program work or error | 0 |
| c) | Hardware maintenance stops | 0 |
| d) | Power jumps and breaks | 2 |
| e) | TOD error correction | 0 |
| f) | Communication lines | 0 |

The total downtime for the period April-August was 35 hours and 23 minutes. The mean-time-between-failures (MTBF) was 51.0 days.

### 2.2 Array Communications

As described in the previous Semiannual Report, the Modcomp/SLEM-based communication system experienced serious problems toward the end of 1993.

As an intermediate solution, it was decided on 1 January 1994 to implement a backup version of the NORSAR recording system, thus eliminating the Modcomp/SLEM-based recording. This change succeeded in improving both the timing reliability and the individual subarray uptimes.

In October 1994, the installation of a new data acquisition system began, in connection with the NORSAR Refurbishment. Details on this installation are given in Section 4.1 of this report.

During the reporting period, the communication lines to all subarrays except 06C were mostly in normal operation, but each of the subarrays was inoperative during parts of the reporting period in connection with testing and preparation for the NORSAR refurbishment. The reason for the extended downtime of subarray 06 C was that this subarray was chosen as the main site for pre-installation testing of digitizers, CIMs and seismometers.

A simplified daily summary of the communications performance for the seven individual subarray lines is summarized, on a month-by-month basis, in Table 2.2.1.

### 2.3 NORSAR Event Detection operation

In Table 2.3 .1 some monthly statistics of the Detection and Event Processor operation are given. The table lists the total number of detections (DPX) triggered by the on-line detector, the total number of detections processed by the automatic event processor (EPX) and the total number of events accepted after analyst review (teleseismic phases, core phases and total).

|  | Total DPX | Total EPX | Accepted events |  | Sum | Daily |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: |
|  |  |  | P-phases | Core <br> Phases |  |  |
| Apr 95 | 10950 | 897 | 355 | 59 | 414 | 13.8 |
| May 95 | 7737 | 1138 | 596 | 85 | 681 | 22.0 |
| Jun 95 | 4231 | 644 | 230 | 51 | 281 | 9.4 |

|  |  |  | 1688 | 339 | 2027 | 13.2 |

Table 2.3.1. Detection and Event Processor statistics, 1 April-30 September 1995.

## NORSAR Detections

The number of detections (phases) reported by the NORSAR detector during day 091, 1995, through day 273,1995 , was 47,110 , giving an average of 293 detections per processed day ( 161 days processed). Table 2.3.2 shows daily and hourly distribution of detections for NORSAR.

NB2 .DPX Hourly distribution of detections

Table 2.3.2. (Page 3 of 4)

Table 2.3.2. Daily and hourly distribution of NORSAR detections. For each day is shown number of detections within each hour of the day and number of detections for that day. The end statistics give total number of detections distributed for each hour and the total sum of detections during the period. The averages show number of processed days, hourly distribution and average per processed day. (Page 4 of 4)

## 3 Operation of Regional Arrays

### 3.1 Recording of NORESS data at NDPC, Kjeller

Table 3.1.1 lists the main outage times and reasons.
The average recording time was $97.79 \%$ as compared to $99.17 \%$ during the previous reporting period.

| Date | Time |  | Cause |
| :---: | :---: | :---: | :---: |
| 04Apr | 2031 | - | Software failure |
| 05 Apr |  | - -0548 |  |
| 20 Apr | 0728 | - 0747 | Power failure |
| 03 May | 0931 | - 1010 | Software failure |
| 05 Jun | 0149 | - 0821 | Hardware failure |
| 13 Jun | 0332 | - 0558 | Software failure |
| 08 Jul | 0002 | - 0836 | Software failure |
| 15 Jul | 0327 | - | Power failure at NDPC due to thunderstorm |
| 16 Jul |  | - 1210 |  |
| 19 Jul | 1821 | - | Hardware failure Hub |
| 20 Jul |  | - 1311 |  |
| 26 Jul | 0117 | - 0635 | Software failure |
| 05 Aug | 0855 | - 2053 | Software failure |
| 07 Aug | 1336 | - | Hardware failure Hub |
| 08 Aug |  | - 0715 |  |
| 19 Aug | 0824 | - 0941 | Software failure |
| 21 Aug | 0617 | - 0630 | Software failure |

Fig. 3.2.1. ARCESS data recording uptime for July (top), August (middle) and September (bottom) 1995.

### 3.3 Recording of FINESS data at NDPC, Kjeller

The average recording time was $98.55 \%$ as compared to $97.8 \%$ for the previous reporting period.

| Date | Time |  | Cause |
| :---: | :---: | :---: | :---: |
| 18 Apr | 0542 | - 0757 | Software failure Helsinki |
| 10 Jun | 1119 | - | Hardware failure Helsinki |
| 11 Jun |  | - 1220 |  |
| 14 Jun | 1351 | - 1427 | Transmission line failure |
| 15 Jul | 0324 | - | Power failure at NDPC due to thunderstorm |
| 16 Jul |  | - 0342 |  |
| 31 Aug | 0658 | - 1059 | Hardware failure Helsinki |
| 11 Sep | 0531 | - 1144 . | Hardware being moved in Helsinki |
| 11 Sep | 1200 | - 1233 | Hardware being moved in Helsinki |

Table 3.3.1. The main interruptions in recording of FINESS data at NDPC, 1 April-30 September 1995.

Monthly uptimes for the FINESS on-line data recording task, taking into account all factors (field installations, transmission lines, data center operation) affecting this task were as follows:

| April 95 | $:$ | $99.68 \%$ |
| :--- | :--- | ---: |
| May | $:$ | $100.00 \%$ |
| June | $\vdots$ | $96.43 \%$ |
| July | $\vdots$ | $96.70 \%$ |
| August | $:$ | $99.46 \%$ |
| September | $:$ | $99.05 \%$ |

Fig. 3.3.1 shows the uptime for the data recording task, or equivalently, the availability of FINESS data in our tape archive, on a day-by-day basis, for the reporting period.
J. Torstveit

Fig. 3.3.1. FINESS data recording uptime for April (top), May (middle) and June (bottom) 1995.

### 3.4 Recording of Spitsbergen data at NDPC, Kjeller

The average recording time was $65.81 \%$ as compared to $96.80 \%$ for the previous reporting period.

The main reasons for downtime follow:

| Date | Time |  | Cause |
| :---: | :---: | :---: | :---: |
| 01 Apr | 0000 | - | Power failure Spitsbergen 31/3 |
| 07 Apr |  | - 1205 |  |
| 08 Apr | 0000 | - 0841 | Software failure |
| 10 Apr | 0900 | - | Hardware failure Spitsbergen |
| 20 Apr |  | - 0718 |  |
| 26 Apr | 1037 | - 1136 | Hardware failure |
| 04 May | 1928 | - 2017 | Communication line failure |
| 05 May | 1001 | - 1143 | Communication line failure |
| 09 May | 0856 | - 0922 | Maintenance Spitsbergen |
| 15 May | 0112 | - 0130 | Communication line failure |
| 15 May | 0443 | - 0506 | Communication line failure |
| 26 May | 0705 | - 0754 | Communication line failure |
| 26 May | 0923 | - 0943 | Communication line failure |
| 26 May | 1115 | - 1151 | Communication line failure |
| 20 Jun | 2053 | - | Hardware failure Spitsbergen |
| 03 Aug |  | - 1950 |  |
| 18 Aug | 0643 | - 0729 | Hardware maintenance NDPC |
| 21 Aug | 1329 | - 1438 | Power breack NDPC |
| 25 Aug | 0946 | - 1118 | Maintenance communication line |
| 04 Sep | 0734 | - 0825 | Software failure |
| 05 Sep | 2105 | - | Software failure |
| 06 Sep |  | - 0621 |  |
| 10 Sep | 0037 | - 0812 | Communication line failure |
| 13 Sep | 0919 | - 0942 | Maintenance communication line |

Table 3.4.1. The main interruptions in recording of Spitsbergen data at NDPC, 1 April 30 September 1995.

Monthly uptimes for the Spitsbergen online data recording task, taking into account all factors (field installations, transmission line, data center operation) affecting this task were as follows:

| April 95 | $:$ | $43.62 \%$ |
| :--- | :--- | ---: |
| May | $:$ | $98.14 \%$ |
| June | $:$ | $65.78 \%$ |
| July | $:$ | $0.00 \%$ |
| August | $\vdots$ | $90.27 \%$ |
| September | $:$ | $97.07 \%$ |

Fig. 3.4.1 shows the uptime for the data recording task, or equivalently, the availability of Spitsbergen data in our tape archive, on a day-by-day basis for the reporting period.

## J. Torstveit

Fig. 3.4.1. Spitsbergen data recording uptime for August (top) and September (bottom) 1995.

### 3.5 Event detection operation

This section reports results from one-array automatic processing using signal processing recipes and "ronapp" recipes for the ep program (NORSAR Sci. Rep. No 2-8889).

Three systems are in parallel operation to associate detected phases and locate events:

1. The ep program with "ronapp" recipes is operated independently on each array to obtain simple one-array automatic solutions.
2. The Generalized Beamforming method (GBF) (see F. Ringdal and T. Kværna (1989), A mulitchannel processing approach to real time network detection, phase association and threshold monitoring, BSSA Vol 79, no 6, 1927-1940) processes the four arrays jointly and presents locations of regional events.
3. The IMS system is operated on the same set of arrivals as ep and GBF and reports also teleseismic events in addition to regional ones.

IMS results are reported in section 3.6.
In addition to these three event association processes, we are running test versions of the so-called Threshold Monitoring (TM) process. This is a process that monitors the seismic amplitude level continuously in time to estimate the upper magnitude limit of an event that might go undetected by the network. Simple displays of so-called threshold curves reveal instants of particular interest; i.e., instants when events above a certain magnitude threshold may have occurred in the target region. Results from the three processes described above are used to help resolve what actually happened during these instances.

## NORESS detections

The number of detections (phases) reported from day 091, 1995, through day 273, 1995, was 36,371 , giving an average of 199 detections per processed day ( 183 days processed).

Table 3.5.1 shows daily and hourly distribution of detections for NORESS.

## Events automatically located by NORESS

During days 091,1995 , through $273,1995,2013$ local and regional events were located by NORESS, based on automatic association of P- and S-type arrivals. This gives an average of 11.0 events per processed day ( 183 days processed). $67 \%$ of these events are within 300 km , and $88 \%$ of these events are within 1000 km .

## ARCESS detections

The number of detections (phases) reported during day 091, 1995, through day 273, 1995, was 86,374 , giving an average of 485 detections per processed day ( 183 days processed).

Table 3.5 .2 shows daily and hourly distribution of detections for ARCESS.

Table 3.5.2 shows daily and hourly distribution of detections for ARCESS.

## Events automatically located by ARCESS

During days 091,1995 , through $273,1995,6187$ local and regional events were located by ARCESS, based on automatic association of P- and S-type arrivals. This gives an average 34.8 events per processed day ( 183 days processed). $57 \%$ of these events are within 300 km , and $87 \%$ of these events are within 1000 km .

## FINESS detections

The number of detections (phases) reported during day 091, 1995, through day 273, 1995, was 41,241 , giving an average of 225 detections per processed day ( 183 days processed).

Table 3.5 .3 shows daily and hourly distribution of detections for FINESS.

## Events automatically located by FINESS

During days 091,1995 , through $273,1995,2456$ local and regional events were located by FINESS, based on automatic association of P - and S-type arrivals. This gives an average of 13.4 events per processed day ( 183 days processed). $80 \%$ of these events are within 300 km , and $91 \%$ of these events are within 1000 km

## GERESS detections

The number of detections (phases) reported from day 091, 1995, through day 273, 1995, was 38,748 , giving an average of 212 detections per processed day ( 183 days processed).

Table 3.5.4 shows daily and hourly distribution of detections for GERESS.

## Events automatically located by GERESS

During days 091,1995 , through 273, 1995, 3917 local and regional events were located by GERESS, based on automatic association of P- and S-type arrivals. This gives an average of 21.4 events per processed day ( 183 days processed). $77 \%$ of these events are within 300 km , and $89 \%$ of these events are within 1000 km .

## Apatity array detections

The number of detections (phases) reported from day 091, 1995, through day 273, 1995, was 114,866 , giving an average of 649 detections per processed day ( 177 days processed).

As described in earlier reports, the data from the Apatity array are transferred by one-way (simplex) radio links to Apatity city. The transmission suffers from radio disturbances that occasionally result in a large number of small data gaps and spikes in the data. In order for
the communication protocol to correct such errors by requesting retransmission of data, a two-way radio link would be needed (duplex radio). However, it should be noted that noise from cultural activities and from the nearby lakes cause most of the unwanted detections. These unwanted detections are "filtered" in the signal processing, as they give seismic velocities that are outside accepted limits for regional and teleseismic phase velocities.

Table 3.5 .5 shows daily and hourly distribution of detections for the Apatity array.

## Events automatically located by the Apatity array

During days 091,1995 , through $273,1995,1309$ local and regional events were located by the Apatity array, based on automatic association of P-and S-type arrivals. This gives an average of 7.4 events per processed day ( 177 days processed). $41 \%$ of these events are within 300 km , and $72 \%$ of these events are within 1000 km .

## Spitsbergen array detections

The number of detections (phases) reported from day 091, 1995, through day 273, 1995, was 126,090 , giving an average of 1009 detections per processed day ( 125 days processed).

Table 3.5.6 shows daily and hourly distribution of detections for the Spitsbergen array.

## Events automatically located by the Spitsbergen array

During days 091,1995 , through $273,1995,12,388$ local and regional events were located by the Spitsbergen array, based on automatic association of P- and S-type arrivals. This gives an average of 99.1 events per processed day ( 125 days processed). $49 \%$ of these events are within 300 km , and $74 \%$ of these events are within 1000 km .

## Hagfors array detections

The number of detections (phases) reported from day 091, 1995, through day 273, 1995, was 48,529 , giving an average of 265 detections per processed day ( 183 days processed).

Table 3.5.7 shows daily and hourly distribution of detections for the Hagfors array

## Events automatically located by the Hagfors array

During days 091,1995 , through $273,1995,1963$ local and regional events were located by the Hagfors array, based on automatic association of P- and S-type arrivals. This gives an average of 10.7 events per processed day ( 183 days processed). $38 \%$ of these events are within 300 km , and $77 \%$ of these events are within 1000 km

Table 3.5.1 (Page 3 of 4)

Table 3.5.1. (Page 4 of 4) Daily and hourly distribution of NORESS detections. For each day is shown number of detections within each hour of the day, and number of detections for that day. The end statistics give total number of detections distributed for each hour and the total sum of detections during the period. The averages show number of processed days, hourly distribution and average per processed day.

Table 3.5.2. (Page 4 of 4) Daily and hourly distribution of ARCESS detections. For each day is shown number of detections within each hour of the day, and number of detections for that day. The end statistics give total number of detections distributed for each hour and the total sum of detections during the period. The averages show number of processed days, hourly distribution and average per processed day.

Table 3.5.3. (Page 4 of 4) Daily and hourly distribution of FINESS detections. For each day is shown number of detections within each hour of the day, and number of detections for that day. The end statistics give total number of detections distributed for each hour and the total sum of detections during the period. The averages show number of processed days, hourly distribution and average per processed day.

Table 3.5.4. (Page 4 of 4) Daily and hourly distribution of GERESS detections. For each day is shown number of detections within each hour of the day, and number of detections for that day. The end statistics give total number of detections distributed for each hour and the total sum of detections during the period. The averages show number of processed days, hourly distribution and average per processed day.

Table 3.5.5.(Page 4 of 4) Daily and hourly distribution of Apatity array detections. For each day is shown number of detections within each hour of the day, and number of detections for that day. The end statistics give total number of detections distributed for each hour and the total sum of detections during the period. The averages show number of processed days, hourly distribution and average per processed day.

Table 3.5.6. (Page 4 of 4) Daily and hourly distribution of Spitsbergen array detections. For each day is shown number of detections within each hour of the day, and number of detections for that day. The end statistics give total number of detections distributed for each hour and the total sum of detections during the period. The averages show number of processed days, hourly distribution and average per processed day.

Table 3.5.7 (Page 3 of 4)

Table 3.5.7. (Page 4 of 4) Daily and hourly distribution of Hagfors array detections. For each day is shown number of detections within each hour of the day, and number of detections for that day. The end statistics give total number of detections distributed for each hour and the total sum of detections during the period. The averages show number of processed days, hourly distribution and average per processed day

### 3.6 IMS operation

The Intelligent Monitoring System (IMS) was installed at NORSAR in December 1989 and was operated at NORSAR from 1 January 1990 for automatic processing of data from ARCESS and NORESS. A second version of IMS that accepts data from an arbitrary number of arrays and single 3 -component stations was installed at NORSAR in October 1991, and regular operation of the system comprising analysis of data from the 4 arrays ARCESS, NORESS, FINESS and GERESS started on 15 October 1991. As opposed to the first version of IMS, the one in current operation also has the capability of locating events at teleseismic distance.

Data from the Apatity array were included on 14 December 1992, and from the Spitsbergen array on 12 January 1994. Detections from the Hagfors array were available to the analysts and could be added manually during analysis from 6 December 1994. After 2 February 1995, Hagfors detections were also used in the automatic phase association.

The operational stability of IMS has been very good during the reporting period. In fact the IMS event processor (pipeline) has had no downtime of its own; i.e., all data available to IMS have been processed by IMS.

## Phase and event statistics

Table 3.6.1 gives a summary of phase detections and events declared by IMS. From top to bottom the table gives the total number of detections by the IMS, the number of detections that are associated with events automatically declared by the IMS, the number of detections that are not associated with any events, the number of events automatically declared by the IMS, the total number of events defined by the analyst, and finally the number of events accepted by the analyst without any changes (i.e., from the set of events automatically declared by the IMS)

Due to reductions in the FY94 funding for IMS activities (relative to previous years), new criteria for event analysis were introduced from 1 January 1994. Since that date, only regional events in areas of special interest (e.g, Spitsbergen, since it is necessary to acquire new knowledge in this region) or other significant events (e.g, felt earthquakes and large industrial explosions) were thoroughly analyzed. Teleseismic events were analyzed as before.

To further reduce the workload on the analysts and to focus on regional events in preparation for Gamma-data submission during GSETT-3, a new processing scheme was introduced on 2 February 1995. The GBF (Generalized Beamforming) program is used as a pre-processor to IMS, and only phases associated to selected events in northern Europe are considered in the automatic IMS phase association. All detections, however, are still available to the analysts and can be added manually during analysis.

There is one exception to the new rule for automatic phase association: all detections from the Spitsbergen array are passed directly on to the IMS. This allows for thorough analysis of all events in the Spitsbergen region.

|  | Apr 95 | May 95 | Jun 95 | Jul 95 | Aug 95 | Sep 95 | Total |

## 4 Improvements and Modifications

### 4.1 NORSAR

## NORSAR data acquisition

The final phase of the NORSAR refurbishment has comprised installation of short period seismometers in the Short Period Vaults - SPVs.

The technical challenge of installing new equipment in the more than 25 year old vaults has been almost overwhelming. The SPV sites are in remote mountain areas with no access roads and no AC power. DC power is obtained through the old buried cables, which are up to 14 km long. Thus DC power supply has been the largest problem. The new seismometer installation requires DC power to the amplifier, the digitizer, the GPS clock and the modems. Numerous experiments and tests have been performed to find and acquire modems, batteries and other electronics necessary to control and operate the seismometer, amplifier and digitizer at the lowest possible power consumption.

The Teledyne Brick Amplifiers 57010-0107 were delivered in July 1995, and the new Teledyne Geotech 20171-0104 instruments were delivered in August 1995.

Patton Electronics modems for transmission of data between the SPV and the Central Terminal Vault - CTV - were delivered in August and October 1995.

During September/October 1995, old electronics and seismometer equipment from 7 CTVs, 7 LPVs (Long Period Vaults) and 42 SPVs have been removed. The sites have thereafter been refurbished with new moisture-resistant paint and new lids.

All electronics have been prepared and mounted in sealed boxes at the Maintenance Center at Hamar for a "plug-in" mode of installation. This has reduced the time of installation, and has allowed completion of the installation during November 1995. The CTV, LPV and SPV sites have been completely rebuilt with respect to instrumentation.

See NORSAR Sci. Rep No. 2-93/94 and NORSAR Sci. Rep No. 2-94/95 for a detailed description of the installations within SPVs and LPVs.

The Science Horizons XAVE data acquisition system has been operating satisfactorily during the intermediate installation period. A block diagram of the digitizer and communication controller components is found in NORSAR Sci. Rep No 2-94/95.

An example of recording from the new instrumentation is shown in Fig. 4.1. A test period with different combinations of gain resulted in using the Brick amplifier together with a gain of 10 in the AIM24 digitizer. This gave the best signal-to-noise ratio for frequencies above 2 Hz .

The NORSAR array has 42 short period seismometers, logically grouped into 7 subarrays. For data requests from stations that participate in GSETT-3, it is usual to have one name
that signifies the full array and then individual station names of the individual components. For NORSAR it is suggested that NORSAR signify the full array, NAO signify all components of subarray 01A, a.s.o. See table 4.1 for the site naming convention for the NORSAR array.

Table 4.1.1. NORSAR site naming. The table shows original subarray names, ISC codes of the center instrument in each subarray and suggested names of each of the 6 SPV sites.

| Old | (Sub)ar- <br> ray name | Site names |
| :--- | :--- | :--- |
|  | NORSAR | All sites within NORSAR |
| 01A | NAO | NA1-00, NA1-01, NA1-02, NA1-03, NA1-04, NA1-05 |
| 01B | NBO | NB1-00, NB1-01, NB1-02, NB1-03, NB1-04, NB1-05 |

## NORSAR detection processing

The NORSAR detection processor has been continuously updated for the differences in acquisition system, and has been running satisfactorily. To maintain consistent detection capability, the NORSAR beam tables have not been changed.

Detection statistics for the NORSAR array are given in section 2.

## NORSAR event processing

The routine processing of NORSAR events as described in NORSAR Sci. Rep No 2-93/94 has been continuously updated for the differences in acquisition system, and has been running satisfactorily.

## J. Fyen

Fig.4.1.1. Schematic illustration of remote SPV electronics. The buried cable between the SPV and the CTV is used for both power and data. The GPS antenna is installed outside the vault, inside a vertical PVC sewage pipe with a lid. The four boxes with electronics all fit into the original zinc-tank vaults. The sensitivity of the 20171-0104 seismometer is $650 \mathrm{~V} / \mathrm{m} / \mathrm{s}$, and a damping of 0.707 is used. The gain of the Brick amplifier is 39.8, and an additional gain of 10 is used in the AIM24 digitizer.

Figure 4.I.2 A Caspian event as recorded by the new short-period instrumentation at NC6-02/sz which is co-located with NRA0/sz. The two lower traces are original data after DC offset removal. The two upper traces are filtered $2-4 \mathrm{~Hz}$.

## 5 Maintenance Activities

## Activities in the field and at the Maintenance Center

This section summarizes the activities at the Maintenance Center (NMC) Hamar, and includes activities related to monitoring and control of the NORSAR teleseismic array, as well as the NORESS, ARCESS, FINESS, GERESS, Apatity, Spitsbergen and Hagfors small-aperture arrays.

Activities involve preventive and corrective maintenance, planning and activities related to the refurbishment of the NORSAR teleseismic array.

## NORSAR

Visits to subarrays in connection with:

- Removal of Guralp broadband instrument, LPV 06C, at completion of test period
- Installation of overvoltage protection at all subarrays
- Repair of power supplies at remote sites after heavy thunderstorm
- Maintenance work on the CTVs and LPVs
- Installation of GPS clocks in LPVs
- Installation of JB-boxes and GPS clocks at remote sites

## NORESS

- Repair of Hub 14 digital card which had been damaged by lightning
- Repair of fiber optical link to remote sites C7 and D7
- Repair of LF-DC synchronized clock
- Repair of broken power supply a remote site B4
- Replacement of CPU card and repair of broken power supply at remote site C5.
- Repair of fiber optical link and power supply are remote sites

## ARCESS

- UPS unit found to be defective. Switched to bypass position (July 95)

## Spitsbergen

- Charged batteries and replaced a defective windmill (April 95)
- Replacement of fuse on RD6 remote digitizer no. 2. RD6 no. 1 found to be defective
- Replacement of RD6 digitizer no. 1 (May 95)
- Installation of Guralp broadband seismometer in borehole B4
- Failure of NORAC data collection device. Sent to NORSAR for repair (June 95)
- NORAC reinstalled in Longyearbyen (July 95). No data received in Longyearbyen over the radiolink due to low battery voltage at the site.

NMC

- Continued the NORSAR refurbishment work

Additional details for the reporting period are provided in Table 5.1.

## 7 Summary of Technical Reports / Papers Published

### 7.1 Analysis of data recorded at the Spitsbergen array

## Introduction

This report presents results from analysis of data recorded at the Spitsbergen array (SPITS) from events in the Svalbard region during the period July through December 1994. Through this period 1258 seismic events in the Svalbard region were manually checked and located using data from the SPITS array.

## Recording Performance

Since the installation of the Spitsbergen array in 1992, the SPITS data have been processed at NORSAR in the following way:

- From 11 December 1992 data from SPITS were included in the manual Intelligent Monitoring System (IMS) analysis when the data quality allowed for it. During the manual review of the automatic IMS results from the processing of data from the other arrays in the northern European region, the NORSAR analysts manually added the relevant SPITS data for the events already defined by the IMS.
- From 12 January 1994 the SPITS data were fully integrated in the IMS and automatically processed in the same way as the data from the other arrays.

Only data that have been manually checked are included in the analysis and shown in the maps in this report.

As indicated in Fig. 7.1.1 the recording performance from July through December 1994 was very good with no month except August having less than $90 \%$ uptime. The low uptime in August reflects the field work performed during 22-31 August, when cables were put in trenches, the $\mathrm{S}-500$ seismometers were replaced with Guralp extended shortperiod (CMG3ES) seismometers and new batteries were installed. Also, a three-component Guralp broad band instrument (CMG-3T) was installed at site B4.

The gain factor and filtering of the new instrumentation was changed on 19 November. For the short period instruments the gain was changed from $6.1 \mu \mathrm{~V} / \mathrm{bit}$ to $0.61 \mu \mathrm{~V} / \mathrm{bit}$, and for the broad band instrument the new gain was set to $1.2 \mu \mathrm{~V} / \mathrm{bit}$. At this visit also the highpass filter corner frequency was changed from 10 to 2 seconds for the short-period instruments. The effect of this change is that we get better on scale recordings of regional seismic events, as can be seen in the difference between the 8 October and 24 November recordings in Figs. 7.1.8 and 7.1.9.

## Detections and Locations

The total number of automatically determined event locations for which data from the SPITS array were used was 1378 events during the 6 months from 1 July through 31 December 1994, whereas the number of manually reviewed locations where SPITS data were used was 1258 .

An overview of the Svalbard region is shown in Fig. 7.1.2, showing the location of the SPITS array and the KBS three-component station. In the same figure the four main mining sites (Pyramiden, Barentsburg, Svea and Gruve 3 \& 7) are indicated.

Figs. 7.1.3 and 7.1.4 show the locations of reviewed seismic events in the period covered as well as those recorded on the array since the installation. The Mohns Ridge and the Knipovitch Ridge show a relatively high seismic activity as should be expected for these parts of the mid-Atlantic spreading ridge system. Possibly more interesting are the clusters of seismic activity on and off shore Svalbard:

1) In the northeast, Nordaustlandet shows a dispersed seismic activity at a relatively high rate, and with a possible $\mathrm{E}-\mathrm{W}$ lineation over the central part.
2) In the Heerland area east of the Svea mine the seismic activity is very high and concentrated within a relatively small area.
3) East of the southern tip of Svalbard, in Storfjorden, a high activity seismic cluster in a relatively small area is found. The activity seems to extend in a northeasterly direction from this cluster.
4) Southeast of Egdeøya (in the Barents Sea) a more dispersed seismic activity is seen.

Some of the seismic clusters above have been recognized by earlier investigators (Bungum et al, 1982; Mitchell et al, 1990), notably the Heer Land zone and the Nordaustlandet seismicity, but also the more dispersed seismicity described under 3) above.

It is also of interest to observe that the Barents Sea south and east of the zone described under 4) seems to be void of seismic activity, and this is also the case for the off shore areas east of the Svalbard Archipelago.

The clustering of seismic events was so intriguing that a cluster analysis of the database was performed in terms of location, magnitude and time of day as shown in Fig. 7.1.5. From this figure it can be concluded that the seismicity shows a clear geographic clustering in the areas mentioned above, but that no clear clustering can be observed in the time of day distribution. This lack of time clustering around certain hours is a very good indicator that the data are real earthquakes and not man-made events, that tend to cluster in certain "firing" hours.

A very crude analysis of the Gutenberg-Richter recurrence parameters was attempted with the $\mathrm{M}_{\mathrm{L}}$ magnitudes calculated. Most of the events in the area $76^{\circ} \mathrm{N}-80^{\circ} \mathrm{N}$ and $10^{\circ} \mathrm{E}-$ $25^{\circ} \mathrm{E}$ had no magnitudes assigned, or had an $\mathrm{m}_{\mathrm{b}}$ magnitude assigned. There were 61 earthquakes with $\mathrm{M}_{\mathrm{L}}$ magnitudes greater than or equal to 2.0. The regression analysis yielded a relation

$$
\begin{equation*}
\log N=4.06+1.25 \cdot M_{L} \tag{1}
\end{equation*}
$$

which for the area under consideration tentatively would indicate return periods of 9 years for magnitude 4 and above and 150 years for magnitude 5 and above. As seen from Fig. 7.1.6 the b value is stable; however, the small amounts of data and the different tectonic environments covered (spreading ridge, oceanic crust and continental crust) certainly warrants further investigations with more data in order to obtain more reliable return periods.

## Data examples

The broad band capability of the new extended short-period Guralp sensors is demonstrated through the records shown in Fig. 7.1.7 of the Chinese nuclear test on 7 October 1994. Figs 7.1.8 and 7.1.9 show SPITS recordings from events on the Knipovitch Ridge and Zone 3 (see list above), respectively. These two events occurred before and after the sensors were changed, and the difference in data quality should be evident. The new Guralp extended short-period sensors provide resolution also of the lower frequencies, where the larger earthquakes are particularly rich in energy. The smaller nearby earthquakes do not have sufficient low frequent energy to exceed the background noise, and hence must be filtered before the signal can be recognized.

Fig. 7.1.7. Recording of the October 7, 1994, Chinese nuclear test at the SPITS array. The upper two records are unfiltered short-period channels for vertical instruments at sites A0 and A1, and the lower two records are the $4-8 \mathrm{~Hz}$ bandpass filtered records for the same two sensors.

Fig. 7.1.8. Recording at SPITS of the 8 October 1994, $3.5 m_{b}$ earthquake on the Knipovitch Ridge $\left(78.2^{\circ} N, 7.8^{\circ} E\right)$

Fig.7.1.9. Recording at SPITS of a 24 November 1994 earthquake off shore and south of the Heer Land Zone ( $77.1^{\circ} N, 17.9^{\circ} E$ ). The upper three channels are raw short-period recordings, whereas the lower three traces are 2-15 Hz band pass filtered data for the same three instruments.

### 7.2 A comparison of the NORSAR array monthly bulletin with the Reviewed Event Bulletin (REB) of the GSETT-3 IDC

## Introduction

The NORSAR teleseismic array has during the fall of 1995 undergone a complete technical refurbishment with respect to its electronic field components (seismometers, analog-to-digital converters and communications interfaces). Following completion of this effort, the NORSAR array will be used as an Alpha (primary) station in GSETT-3 and thus be among the stations that determine the event detection capability of the GSETT-3 network.

In order to assess the future contributions of the NORSAR array in GSETT-3, we have compared the REB issued by the GSETT-3 IDC with the NORSAR array bulletin for the period January - August 1995. The NORSAR bulletin is issued on a monthly basis and comprises events detected and located by the NORSAR teleseismic array on a stand-alone basis. During January - August 1995 the NORSAR array was operated in a temporary configuration, using the old HS-10 short period seismometers and Nanometrics RD-6 18-bit digitizers.

The comparison between the REB and the NORSAR monthly bulletin involved the determination of events in the REB that were not in the NORSAR bulletin, events that were clearly common but where the event solutions differed substantially, and events in the NORSAR bulletin for which there were no counterparts in the REB. Only events in the latter category are dealt with in this short contribution.

## Analysis and discussion

Table 7.2.1 lists 207 events from the NORSAR bulletin during January - August 1995 for which there are no corresponding events in the GSETT-3 REB. The events in this table are plotted in Fig. 7.2.1. Most of the events are seen to cluster in four areas: the Balkans, Hindukush, Japan and the Kuriles, and the Fiji-Tonga-Kermadec area.

Based on their long experience with data from the NORSAR array, our analysts believe all 207 events in Table 7.2.1 to be real ones. Note, however, that the event epicenters may have an uncertainty of up to several hundred kilometers, as they are based on apparent velocities and arrival azimuths measured at one array station only. Only 11 of these 207 events are confirmed by the PDE bulletin, and the relevant PDE solutions are also given in Table 7.2.1.

For an event to appear in the REB it must have defining P-phases from three or more primary stations of the GSETT-3 network. The primary stations of the GSETT-3 network as of 26 August 1995 are shown in Fig. 7.2.2. The estimated detection capability of this network is shown in Fig. 7.2.3. The theoretical detection threshold for all four regions named above are seen in Fig. 7.2.3 to be at magnitude 4 and above, in terms of a $90 \%$ probability of P-wave detection at three primary stations in the GSETT-3 network.

By inspecting the magnitudes for the events in Table 7.2.1, one finds that the large majority of the events have magnitudes below the theoretical detection threshold of the GSETT3 network in place by the end of the time interval under study. A few events in the Balkan area, however, do have NORSAR magnitudes slightly above the GSETT-3 neiwork threshold. These events are from the Greece earthquake sequence in May 1995, which has been studied in detail by Ringdal (1995). The fact that a few events above the $90 \%$ threshold have not been reported is of course not necessarily a contradiction, and as shown in the mentioned paper, the REB detectability for the Balkan area is consistent with the theoretical estimates inferred from Fig. 7.2.3. Some events in the Japan-Kuriles region have NORSAR magnitudes of the order of the network threshold or slightly above, but again, this is to be expected. In general, our data confirm the validity of the theoretically estimated GSETT-3 detection capability.

## Conclusion

Taking into account the uncertainty in the magnitude estimates, one may conclude that this investigation has qualitatively confirmed the theoretical detection thresholds of the GSETT-3 network in the four regions considered. Also, it shows that introduction of the NORSAR teleseismic array in the GSETT-3 primary network in the near future holds promise that more events from these four regions will enter the REB. In this connection, it should be noted that the on-going implementation of an improved NORSAR detector algorithm (Fyen et al, 1995) might add further events from areas where the NORSAR array is especially sensitive.

Fig. 7.2.1. This figure shows 207 events in the NORSAR bulletin for the period January - August 1995 for which there are no corresponding events in the REB of the GSETT-3 IDC.

Fig. 7.2.2. This figure shows the GSETT-3 primary station network as of 26 August 1995. Array stations and 3-C stations are marked as circles and triangles, respectively. The figure is taken from the IDC Performance Report for the period 13-26 August 1995.

Fig. 7.2.3. The map shows the estimated detection capability of the GSETT-3 primary station network shown in Fig. 7.2.2. The contours show the detection capability in terms of $90 \%$ probability for $P$-wave detections on three GSETT-3 primary stations. The solid circle, plus signs and asterisks denote events found in the QED, but not in the REB (see the IDC Performance Report for the period 13-26 August 1995, from which this figure is reproduced, for further details).

### 7.3 Development of improved NORSAR time delay corrections

## Introduction

The large aperture NORSAR array began operation in 1970, and comprised initially a configuration of 22 subarrays distributed over a diameter of 100 km . After six years of experimental operation, the array was modified on 1 October 1976 to a reduced configuration which was more suitable for an automated, operational system, and the 7 best subarrays (in the NE part of the original array) were selected for this purpose. This configuration is still in operation today, with each subarray comprising 6 SP and one 3-component BB seismometer over an area 8 km in diameter. The total aperture of NORSAR is now 60 km (Fig. 7.3.1).

A complete technical refurbishment of the NORSAR array was carried out during 19921995, and the array will in 1996 be ready for participation in the GSETT-3 experiment. However, in order to take full advantage of the NORSAR capabilities, it is desirable to update the beam deployment and revise the time delay anomalies taking into account the improved precision made possible from the increased sampling rate ( 40 Hz against previously 20 Hz ) and the accumulated data base of reference events. This paper gives a progress report on the work carried out until now and should be seen in connection with previous reports on this subject (Fyen, 1995a, 1995b).

## Procedure

The main points of revising the NORSAR beam deployment, as described in more detail in Fyen (1995a) are summarized as follows:

## Data base development

We are compiling a data base of several hundred well-recorded and well-located events, dating back to the initial NORSAR establishment in 1970. Emphasis is on obtaining a good geographical distribution of epicenters. Among the events of special interest here will of course be the known nuclear explosions, especially the large number of PNEs in the former Soviet Union.

## Reference locations

We have primarily made use of ISC or PDE location estimates for reference purposes. In cases where more accurate locations have been published (e.g., in recent literature or in local bulletins), these locations will be used. Additionally, location of recent events calculated by the GSETT-3 IDC is a helpful supplement.

## Channel correlation

The reference events are systematically analyzed using a semi-automated channel correlation procedure, and verified by an experienced analyst. The correlation is based on the first cycle(s) of the P -signal, in an optimum filter band. A resampling procedure is applied before the correlation in order to improve the timing resolution.

## Consistency checking of the delay anomalies

By using several reference events from nearby locations, it will be possible to make a systematic search for outliers. This procedure ensures that the data are consistent to the extent possible.

## Interpolation in inverse velocity space

As originally done by IBM in the LASA/NORSAR development (Berteussen, 1974), the data base of time delay anomalies will, if necessary, be subjected to two-dimensional interpolation in inverse velocity space, to obtain anomaly estimates for regions in which no events have been recorded. For many regions, we expect the coverage to be dense enough so that interpolation is unnecessary.

## Beam deployment

A revised beam deployment for NORSAR is being developed on the basis of the results of this study. The beamforming gain at various frequencies has been compared to the previous beams, so as to quantify the improvements achieved by this project.

## Use of single-sensor anomalies

In contrast to the original time delay anomalies for NORSAR, which were developed only for subarray beams, the new set of delays are compiled as far as possible on an individual seismometer basis. This implies that even detection at the subarray level should be significantly improved, especially at high frequencies. However, in some regions the SNRs of the reference events are insufficient for single sensor analysis, and subarray beams are used in these cases.

For further details on NORSAR detection processing, slowness estimation and measurement of time delay anomalies, reference is made to Fyen (1995a).

## Data analysis

## Data base

The data base analyzed so far comprises 55 reference events, as listed in Table 7.3.1. The events are distributed globally, but for some areas several close events have been analyzed in order to compare the consistency of the results.

## Correlation procedure

For each event, an interactive correlation procedure was carried out, as described by Fyen (1995a) and illustrated in Figs. 7.3.2 and 7.3.3. The first of these figures illustrates time picks within one subarray, whereas the second figure shows time-aligned traces from the entire array after automatic waveform correlation. It is seen that the correlation is excellent for the first two cycles, whereas scattering effects cause the remainder of the wavetrain to be far less coherent across the array.

## Location anomalies

For each event, a plane wave was fitted by least squares, using the final time picks. This enabled us to calculate an "uncalibrated" location based on observed azimuth and velocity (using IASPEI tables to convert velocity to distance). Fig. 7.3.4 compares these uncalibrated locations with the "true" location of the reference events. Not unexpectedly, the azimuth is relatively more reliable than the distance, but even the azimuth needs correction in some cases. The location errors are generally quite consistent over limited areas, implying that consistent correction will be possible to apply.

## SNR gains

We expect that the SNR gains achieved by the new time delay corrections will be significant for events of dominant high frequencies. The new time delays will make full array processing feasible in a filter band as high as $2-4 \mathrm{~Hz}$, as compared to the current 1.23.2 Hz filter. Fig. 7.3.5 shows the relative SNR on the array beam for the 55 reference events using 2-4 Hz filter with the new corrections and $1.2-3.2 \mathrm{~Hz}$ for the old corrections. In some cases, a gain by a factor of $5\left(0.7 \mathrm{~m}_{\mathrm{b}}\right.$ units) is observed. It is also seen that for some events (with low-frequency signal content) the 1.2-3.2 filter is still better than 2-4 Hz . This shows that it will be necessary to apply a set of narrow band filters for optimum detectability, similar to what is done for the NORESS-type arrays.

The new time delays are in general not expected to give large gains in the $1.2-3.2 \mathrm{~Hz}$ band for areas where the old calibration data base is well developed. For example, Fig. 7.3.6 shows array beam (new and old time delays) for a scaled-down signal (a factor of 200) from a Lop Nor explosion. The SNR for the new set is slightly better, but not by a large amount. Nevertheless, the new time delays should give significant gain in the $1.2-3.2 \mathrm{~Hz}$ band for areas where the old data base is less well established, and this will be investigated further.

## Future plans

The data base will be extended to comprise several hundred well-recorded events, using the same analysis procedures as described above. This is expected to provide significantly more accurate azimuth/velocity estimates for detected events world wide, and would also contribute to improved detectability by enabling full NORSAR array processing in additional high-frequency filter bands.

Table 7.3.1. List of events used in this study.

Fig. 7.3.1. Configuration of the large aperture array NORSAR and small aperture array NORESS. The NORESS array is co-located with the NORSAR subarray 06C. The diameter of NORSAR is about 60 km and the diameter of NORESS is about 3 km . Each instrument site is marked with a circle and a cross.

Fig. 7.3.2. NORSAR interactive tool for time picks. A trace-cursor containing the reference trace with reference arrivaltime mark is available to the user, but not visible on this figure. Using this cursor, the analyst can easily correlate the signals to find best arrival time pick.

Fig. 7.3.3. NORSAR single sensors filtered 1.2-3.2 Hz and shifted with time delays picked by automatic correlation. Traces are plotted on top of each other in the same amplitude scale. The resulting least squares plane-wave fit gives: Observed velocity 16.44, azimuth 79.73; Calibrated velocity 17.37, azimuth 77.80; IASPEI velocity 14.48, azimuth 76.13.

Fig. 7.3.4. Map of reference events used in analysis. The circles correspond to ISC/PDE locations. The triangles show locations corresponding to slownesses estimated by least squares fit to observed time delays.

SNR 2.0-4.0 Hz relative to SNR(old) $1.2-3.2 \mathrm{~Hz}$

Fig. 7.3.5. Relative SNR between best beam using filter 2.0-4.0 Hz and new time delays and best beam using filter $1.2-3.2 \mathrm{~Hz}$ and old time delays.

Fig. 7.3.6. NORSAR signal from the 15 May 1995 Lop Nor explosion scaled down by factor of 200 and added to noise preceding main onset. The upper trace shows resulting beam after beampacking using filter 1.2-3.2 and old time delay corrections. The observed velocity and azimuth is 12.27, 73.47. The lower trace is resulting beam from beampacking using new time delay corrections. Resulting observed velocity and azimuth is 14.84, 77.57. IASPEI theoretical values are 14.48, 76.13.

### 7.4 Automatic onset time estimation based on autoregressive processing

## Introduction

In order to support the developments at the GSETT-3 IDC, we have during this reporting period been experimenting with the use of an autoregressive method for automatic onset time estimation, denoted AR-AIC. This method has for several years been operational in the processing of data from the Japanese national seismic network, and the software has been provided to us by scientists from the Japanese NDC.

In this paper we have adapted the Japanese method for application to GSETT-3 data, with emphasis on developing an automated procedure that includes new features such as multiple narrow-band filters, the concept of "usable bandwidth" and a quality measure of the estimated onset time.

## IDC onset time estimation

We have investigated the automatic phase picking at the GSETT-3 IDC, and found that the automatic picks are consistently late compared to the onset times determined by the analysts. Fig. 7.4.1 shows some characteristic examples where the automatic onsets, denoted $\mathbf{S}$, are all late. In order to quantify the bias of the automatic phase picking procedure at the IDC, we have in Fig. 7.4.2 plotted the time difference between manual and automatic onsets for all P-phases with SNR > 50 for the time period January-September 1995. We see that the automatic onsets are usually late for the entire time interval, and this behavior becomes even more pronounced during the last 3 months of the period.

A new signal processing package which is scheduled to be installed at the GSETT-3 IDC will hopefully take care of the deficiencies of the current procedure used for onset time estimation. It should be noted that the current onset estimation procedure has been adapted from the algorithm used for automatic arrival time picking at NORSAR (Mykkeltveit \& Bungum, 1984), and also that our experience is that the implementation at NORSAR does not provide such delayed onsets.

## Autoregressive method

We will first give a brief description of the Japanese autoregressive method for onset time estimation, and for details we refer to Kamigaichi (1994), GSE/JAPAN/40 (1992), Yokota et al (1981) and Maeda (1985).

Generally speaking, autoregressive (AR) models are employed to represent the seismic waves, and Akaike's Information Criterion (AIC) is used to determine the AR order and to estimate the arrival times of the seismic signals.

Fig. 7.4.3 illustrates the basic concepts of the method:

- An initial onset is given, either from the time of the declared STA/LTA-based signal detection or from another onset time estimator. The original data is shown in the lower panel of Fig. 7.4.3.
- AR coefficients are computed from data in two windows, one located in the noise preceding the initial onset ( F -window) and another located within the signal ( S -window).
- The data are filtered with two prediction error filters, derived from the AR coefficients of the F- and S-windows, respectively (see 2nd and 3rd panel of Fig. 7.4.3).
- Finally, the Akaike Information Criterion (AIC) (see upper panel) is applied as a criterion to estimate the optimal division point of the time series. This division point will be the minimum of the AIC-curve, and is taken to be the onset of the seismic signal.

The F-window was in this study defined to start 7 s ahead of the initial onset, whereas the S -window started 1 s after the initial onset. Both windows had a length of 4 s . As seen from Fig. 7.4.3, the AIC was computed for a 12 s interval, starting 7 s ahead of the initial onset. This parameterization can, of course, be adjusted to accommodate different types of applications of the method.

We will in the following discuss the AIC onset time estimation utilizing the AR-coefficients of both F- and S-windows. There is also an option for utilizing the AR-coefficients of the F-window only. This option will in the text be referred to as AIC $_{F}$ or AR-AIC ${ }_{F}$

## Performance for high SNR teleseismic signals

As a first evaluation of AR-AIC, we analyzed teleseismic GSETT-3 data with high SNR, primarily P-phases from the Chinese nuclear test on 17 August 1995. First, we picked the phase onsets manually on the raw unfiltered waveforms using the NORSAR analysis tool, EP, with high resolution graphics (Fyen, 1989). Secondly, we ran the AR-AIC method on the same data set, using the automatic onsets from the IDC processing as the initial start time. The results are shown is shown in Fig. 7.4.4, and we see that there is an excellent correspondence between the manual and AR-AIC onset estimates for these high SNR teleseismic signals. The mean time difference is less than 2 milliseconds and the standard deviation is 0.04 s . As a result of this close correspondence, we will in the following use these AR-AIC onsets as the reference. The reason for this change of reference is purely due to convenience, as we in this way avoided retyping the manual onsets.

In Fig. 7.4.5, we show the time difference between the AR-AIC onsets and the automatic (SigPro) time picks at the IDC. As expected from the results given in Fig. 7.4.2, the automatic onsets are consistently late, with a mean time difference of 0.45 s .

Similarly, we compared the analyst reviewed IDC picks with the AR-AIC onset (and indirectly also the manual picks using the EP program). The results are shown in Fig. 7.4.6, and we see that for this data set the manual picks at the IDC are often early, with a mean of about 0.2 s . We also see from the figure that there is a sub-set of the data which is in quite close agreement, whereas another sub-set is about 0.3 s early. We do not know the reason
for this time difference, but there are two factors that can be of importance. One is the limited time the IDC analysts are able to spend on refining the time picks due to the daily workload. Another possible source of error is the compensation for the group delay of the bandpass filters used prior to the phase picking. This is a topic that should be revisited, as the current procedure for time adjustment due to the group delay of the bandpass filters clearly has deficiencies.

## Implementation of AR-AIC for processing of GSETT-3 data

From applying the AR-AIC method to signals with various frequency contents, signal-to-noise ratios and complexities, we found that some preprocessing was necessary to ensure stable performance of AR-AIC. In particular, an assessment of the usable bandwidth of the signal, followed by bandpass filtering and decimation was necessary when processing low SNR signals, especially at low frequencies. Once the onset time was estimated, we found it helpful to calculate an accompanying quality measure. The idea behind this quality measure was to have a tool that could be used to automatically distinguish between "good" and "bad" onsets, and possibly also to get an associated uncertainty. The flowchart for automatic operation of AR-AIC is given in Fig. 7.4.7. We will in the following describe in more detail the procedures for the assessment of the usable signal bandwidth and the quality of the AR-AIC onset.

## Usable bandwidth

The estimation of the usable bandwidth of the signal was done by filtering the signal with a set of relatively narrow bandpass filters, and then for each of these filters we computed the maximum SNR (STA/LTA) within a time interval around the initial onset. The usable bandwidth was then estimated from a comparison between the maximum SNR's of the different filter bands. Specifically,

- We estimated the maximum SNR within the time interval ( $s-2, s+3$ ) sec. for a set of narrow bandpass filers, where $s$ is the initial onset time. The 3rd order Butterworth filters used in this study were (in Hz ): 0.5-1.5, 0.8-1.8, 1.0-2.0, 1.5-3.0, 2.0-4.0, 3.0-5.0, 4.06.0, 6.0-8.0, $8.0-10.0,10.0-16.0,14.0-20.0$. The high end of the filter bands were limited by the Nyquist frequency.
- We then found the filter band providing the highest $\operatorname{SNR}$, called SNR $_{\text {max }}$. If the neighboring filters had SNRs within a factor 5 of $S_{\max }$ and at the same time had $S N R>4.5$, then the usable bandwidth was extended to include these neighboring filter bands.

An example illustrating the algorithm is given in Table 7.4.1. It should be noticed that no rigorous testing has been conducted to come up with the parameters of this algorithm, but they are derived from experiments with limited data sets and from our experience with processing of seismological data.

After having estimated the usable bandwidth of the signal, we filtered the data with a 2 nd order Butterworth filter for this bandwidth, and then decimated the data in accordance with the high cutoff frequency of the bandpass filter. The necessity of doing filtering and decimation for processing of low SNR signals is illustrated in Fig. 7.4.8. This signal does only have a usable SNR in the filter band $1.0-2.0 \mathrm{~Hz}$, as shown in the lower panel. The result from applying AR-AIC to the unfiltered data is shown in the upper panel, where $\mathbf{S}$ is the initial onset time and $\mathbf{A}$ is the

AR-AIC onset. The second panel shows the result after filtering, but without decimation, and, finally, the third panel shows the result after both filtering and decimation. Obviously, the AR-AlC onset after filtering and decimation gives the best result.

We have also made some preliminary tests on how the application of this 2nd order causal Butterworth filter for the usable bandwidth influenced the arrival time estimates. The high SNR P-phases that were previously analyzed as shown in Fig. 7.4.4, were bandpass filtered and decimated prior to AR-AIC processing. The time differences between AR-AIC computed on unfiltered data and data filtered in the usable bandwidth are shown in Fig. 7.4.9. For this data set we can see that there is no need to introduce any corrections for the filter. But before drawing any definite conclusions on the filter effects on the onset time estimates, we need to investigate more thoroughly the effect of varying SNR, bandwidth, filter order and signal frequency content.

## Quality of the onset time estimates

The uncertainty of manually determined phase onsets is obviously dependent on the SNR of the signal. In addition, manual phase picks are often accompanied with a flag indicating the instantaneous or emergent nature of the arrival.

We have during our work with the AR-AIC method found that it would be very valuable to attach to the automatically determined onsets some additional parameters that can subsequently be used to derive associated picking uncertainties. In addition, we would like to know the degree of success of the estimation procedure, e.g. in terms of a flag indicating whether the algorithm truly succeeded or possibly failed.

The human observation of a seismic phase is attributed to an amplitude increase and/or a change in the frequency content of the data. If the trace is properly filtered, an amplitude increase should be observable. In this study, we have therefore decided to derive additional signal parameters from the time domain data, filtered in the band that provides the highest SNR. To analyze the amplitude increase we found it convenient to create the envelope of the data from the bandpass filtered trace and its Hilbert transformed counterpart. The Hilbert envelope was gently smoothed with a lowpass filter. This procedure is illustrated in Fig. 7.4.10.

We defined the following set of measurements to be made on the envelope:

- NOISE $_{\text {max }}$ was taken to be the maximum of the envelope within a 3 second interval preceding the automatically estimated onset.
- $\mathrm{AMP}_{0.5}, \mathrm{AMP}_{1.0}, \mathrm{AMP}_{2.0}, \mathrm{AMP}_{3.0}$ and $\mathrm{AMP}_{5.0}$ were the maximum of the envelope within $0.5,1.0,2.0,3.0$ and 5.0 seconds after the onset, respectively. The corresponding (quality) signal-to-noise ratios $\operatorname{QSNR}_{0.5, \ldots, 5.0}$ were defined to be $\mathrm{AMP}_{0.5, \ldots, 5.0}$ NOISE $_{\text {max. }}$
- $\mathrm{T}_{\mathrm{QSNR1.5}}$ was the time from the onset to the point where QSNR exceeded 1.5. $\mathrm{QSNR}_{\mathrm{fp}}$ was the signal to noise ratio of the first local peak of the Hilbert envelope in an interval from $T_{\text {QSNR1.5 }}$ to 5 seconds after the onset. $\mathrm{T}_{\mathrm{fp}}$ were the time from the onset to the first local peak, and $\mathrm{T}_{\text {max }}$ were the time from the onset to the point where the maximum QSNR was found (within 5 seconds of the onset).

When searching for the best frequency band for bandpass filtering, we searched among the same filters as those used for determining the usable bandwidth, but we did now use $\mathrm{QSNR}_{3.0}$ as the criterion for determining the best filter.

In order to get an idea on how to use the envelope measurements to quantify the quality of the automatic AR-AIC onsets, we analyzed a limited data set of 122 phases associated to events in the IDC Reviewed Event Bulletin (REB). The onsets of all phases were manually picked by using the EP program to get a reference for comparing the automatic onsets. Fig. 7.4.11 shows the difference between the AR-AIC, hereafter also denoted AR-AIC $\mathrm{F}_{+}$, onsets and the manual picks as a function of $\mathrm{QSNR}_{2.0}$. The data points labelled $\mathbf{F}$ represent phases that we were unable to pick manually in a confident way, primarily due to low SNR. We see from the figure that for QSNR $_{2.0}$ lower than 5, the scatter increases significantly, as the algorithm had a tendency to make an early trigger. An interesting observation during our testing was that the AR-AIC ${ }_{F}$ method, utilizing only the autoregressive coefficients of the preceding noise window, often gave the correct onset in the cases where $\mathrm{AR}-\mathrm{AIC}_{\mathrm{F}+\mathrm{S}}$ made the wrong decision. For this data set, we found that by using the time difference between the two types of AR-AIC onsets together with the quality measurements $\mathrm{QSNR}_{0.5}, \mathrm{~T}_{\mathrm{QSNR} 1.5}$ and $\mathrm{SNR}_{\text {max }}$, we were able to obtain a rule for identifying the cases where we should use the AR-AIC $F_{F}$ onset instead of $A R-A I C_{F+S}$. The results are given in Fig. 7.4.12, and we clearly see that the scatter at low SNR is significantly reduced (except for the low quality $\mathbf{F}$ onsets).

In automatic operation of AR-AIC it is important to identify the cases where the method failed as well as the cases where the phase onsets are very uncertain. First of all, the phases that we were unable. to pick manually, labelled $\mathbf{F}$, should be identified as a low quality onset. From utilizing the quality measurements $\mathrm{T}_{\mathrm{QSNR} 1.5}$, QSNR $_{5.0}$ and the time difference between the initial onset and the AR-AIC onset, we were able to categorize as low quality 20 out of 22 F onsets, while retaining 90 out of 100 acceptable onsets. The results are shown in Figs. 7.4.13 and 7.4.14. As expected, we see from Fig. 7.4.13 that the time difference between the manual and the automatic onsets decreases with increasing $\mathrm{QSNR}_{2.0}$. As an illustration, we separated the data into two populations based on a QSNR 2.0 of 6 , and found that the standard deviation was 0.15 s for the high SNR population and 0.5 s for the low SNR population.

We have with this example shown that it is possible to use the envelope quality measurements to indicate how well the automatic AR-AIC onsets match the manual picks, as well as a tool to identify low quality onsets. In addition, the envelope quality measurements were used to decide between the use of $A R-A I C_{F 4 S}$ and $A R-A I C_{F}$ A next step will be to analyze a larger data set that also contains detections that are unassociated to seismic events. In this way we can get a better picture of the operational performance of AR-AIC and the associated quality measurements.

## Conclusions

We have in this study shown that by including processes like determination of usable bandwidth, filtering, decimation and quality assessments, the AR-AIC method for onset time estimation can be adapted to work on a wide range of seismic signals. In particular, we have found it convenient to be able to distinguish between reliable and unreliable
onsets. In this way, we can avoid using erroneous arrival time data in the subsequent event location procedures, and thus being able to improve the location precision of the automatic processing system.

It is also our goal to be able to give more weight to the most reliable phase onsets. In the location procedure at the IDC this is done by associating the arrival times with a given uncertainty, currently being only a function of phase type. In order to investigate how the uncertainty of the AR-AIC onsets depends on the envelope quality measurements described above, it is necessary to analyze events for which ground truth information is available, e.g. in terms of accurate locations provided by local networks. During the next reporting period we plan to conduct such a study for a set of events located in the Japan area, with high quality locations provided by the Japanese National Seismic Network.

### 7.5 Recommendation on Auxiliary Seismic Stations for the IMS Network

This contribution is a lightly edited version of a paper prepared by the GSETT-3 Working Group on Planning (WGP) in preparation for the 42nd GSE session in Geneva during 27 November - 1 December 1995. The main purpose of this GSE meeting was to make a specific recommendation for the auxiliary seismic network of the International Monitoring System (IMS), which will be installed to verify compliance with a Comprehensive Test Ban Treaty.

## Introduction

In its progress report of the 41st session, the GSE decided on a work plan for the GSE meeting from 27 November through 1 December. One of the tasks contained therein is to recommend a list of auxiliary stations for the seismic component of the IMS network based on the experience in GSETT-3.

In a letter to the GSE delegates on 26 September 1995, the GSE Chairman, Ola Dahlman, informed the GSE of the Ad Hoc Committee's expressed desire that the GSE submit, as one of the results of its forthcoming session, 27 November - 1 December, sufficient technical material to enable the IMS Expert Group, which is scheduled to meet the following two weeks, to agree on a list of auxiliary stations for the IMS. This will then facilitate subsequent decisions on the network by the Ad Hoc Committee.

In the same letter the GSE Chairman asked the Working Group on Planning to start work on a list of auxiliary stations, and to provide an initial recommendation for the auxiliary network at the beginning of the 42nd session. The status of this work was addressed at a GSE Convenors' meeting in Lahti, Finland, on 14 October 1995, and was also discussed in a coordination meeting between the Working Group on Evaluation (WGE) and the WGP in Paris on 7 November 1995.

This report provides the preliminary recommendation from the WGP and is intended as a basis for discussions during this GSE session. The network designs proposed herein will be reviewed and revised during the GSE session as additional information is received from GSE participants. Material on relevant experience from GSETT-3 will also be taken into account in the process of selecting a recommended IMS auxiliary network.

Much of the basis for the work of defining an IMS auxiliary station network was provided by the agreement reached in the Seismic Experts Group meetings held in Geneva during the week following the August 1995 GSE session. As a result of this work, there is already agreement in the NTB AHC on a specific 50 -station primary seismic network for IMS (see CD/NTB/WP.269, pp. 4-9 and CD/1364, pp. 92-94). There is also agreement on the purposes of the auxiliary network, and on the basic principles/seismological procedures for selecting stations of an auxiliary seismic network to complement the IMS primary network in the best possible way (CD/NTB/WP.269, pp. 10-14).

## Purposes of the Auxiliary Network

CD/NTB/WP. 269 states that there are two principal purposes for the data that will be provided by the IMS auxiliary network:

- to improve the location accuracy of seismic events detected by the primary network
- to more finely characterize the seismic sources for purposes of event identification.

CD/NTB/WP. 269 states that it is a goal to reduce the event location uncertainty to an area equivalent to less than 1,000 square kilometers, as a result of the combined use of primary and auxiliary station data at the IDC. CD/NTB/WP. 269 also states that the auxiliary stations that are used to improve the event location, plus additional ones if full azimuthal coverage is lacking, will be used in the computation of source characterization parameters.

## Station Selection Criteria and Procedures

CD/NTB/WP. 269 states that

- auxiliary stations should primarily cover the seismically most active regions of the world, with emphasis on regions where earthquakes look explosion-like
- auxiliary stations should also be located in regions where there is extensive mining activity that produces large seismic signals
- auxiliary stations should further be located in areas where the azimuthal coverage of the primary station network is poor
- auxiliary stations should be selected from stations that are already available or can be adopted with a minimum of new investment.

Another factor to take into account in the selection process is the statement in CD/NTB/ WP. 269 that "stations in the auxiliary network should be able to act as a backup to stations in the primary network should an extended problem with a primary station arise". This might be interpreted to mean that some of the auxiliary network stations should be especially selected so as to have signal detection capabilities similar to those of the primary network stations, so they could be useful substitutes for one or several primary stations in the same region.

## Preparatory Work by the WGP

WGP has been compiling information on stations around the world that might be candidates for the IMS auxiliary network. As part of this survey, the WGP contacted all GSE delegations and asked for information on candidate stations in the various countries. In addition, updated lists of stations of the member networks of the FDSN have been obtained from various sources.

Information on worldwide mining activity has been obtained from various sources. This material shows that world minerals production is dominated by the United States, China, Chile and Russia. We have also obtained a list of eighteen other countries with major
minerals production. Data on actual blasting practices are generally unavailable on a mine-by-mine basis. Therefore, regions having potential for large blast activity are best identified based on mine location and minerals production data. It must be noted here that we are only concerned with blasting activity that is detected and located by the primary seismic network. As an example here, this rules out some large, known shots in Canada, as it is known that these shots (of the order of 0.5 kt or more of chemical explosives) are not defined by the GSETT-3 Alpha network, and the IMS primary network will be even more sparse in the Canadian region.

The WGP has provided the WGE with four possible IMS auxiliary network designs; of 75, 100,130 and 150 stations, respectively. According to the agreed division of labor between the WGP and the WGE, the WGE has made assessments as to which of these networks would be the most adequate for IMS. The WGE has focused on assessment of the expected event location uncertainties for the various designs, using different approaches, and on azimuthal coverage, using the so-called "octant approach". Their findings are presented in GSE/WGE/14, along with discussions of assumptions and limitations associated with this kind of assessment.

## Network Recommendations

To accommodate all expert views expressed in CD/NTB/WP. 269 regarding the number of stations in the IMS auxiliary seismic network, two possible designs are presented in the following (CD/NTB/WP.269, page 12: "Some experts expressed the view that up to 100 auxiliary stations would be needed, while others considered that between 100 and 150 stations would be necessary").

Table 7.5.1 lists 130 stations preliminarily proposed for the IMS auxiliary network, and in addition defines a subgroup of 100 stations, which in our view would be an optimum subset of this network. The two networks thus defined in this table are slightly revised relative to the 100 - and 130 -station networks that were provided to the WGE for their assessment, but the general capabilities of the corresponding networks are the same.

Table 7.5.1 provides details on the stations of these designs. The table gives the rationale for the inclusion of the various stations, in accordance with the station selection criteria and procedures outlined above. The meaning of the entries in the "Rationale" column of this table is as follows:

S : Station is in a seismically active region
M : Station is in an area of extensive mining
C : Station is in an area where the azimuthal coverage of the primary station network is poor

B : Station could serve as a backup for one or several primary stations (would then need to have continuous communications).

The "status" column of the table gives the operational status of the stations, with codes as follows:

ED : Existing digital station (note that communications link may not be in place)
PL : Planned digital station
PR : Proposed digital station
EA : Existing analog station
The proposed stations are shown as yellow triangles in Fig. 7.5.1, which also shows the IMS primary stations as dark blue squares. As seen in the figure, there is a distinction between the stations in the subgroup defining the 100 -station network, and the additional 30 ones that are only in the proposed 130 -station network (inverted triangles in the latter category). The stations are plotted against the background of world seismicity, here represented by 16,900 REB epicenters from 1 January 1995 through 11 November 1995.

## Features of the 100-Station Design

- This design has 66 stations to cover the major seismic zones of the world. Some of these 66 stations also cover mining activity.
- 34 stations of this design are introduced to improve the overall azimuthal coverage, and/or located in regions of extensive mining activity.
- 13 out of these 100 stations have been assigned the role of providing backup for primary stations. These stations would need to have equipment for continuous transmission of data to the IDC.
- This design has a very limited coverage in ocean areas, and relies on synergy with the IMS hydroacoustic component for adequate performance in these areas.
- The location uncertainty area of this network design as simulated by the WGE is of the order of or smaller than $1,000 \mathrm{~km}^{2}$ in the interior of all large landmasses except the Antarctica, but exceeds this number in the onshore parts of continental margin areas and in the oceans. It should be noted, however, that simulated network capabilities are generally on the optimistic side, due to several underlying idealistic assumptions made, one of which is that of a fully calibrated network.
- The worldwide octant coverage for this design is between 4 and 5. The WGE considers that a number of 5 or higher indicates good azimuthal coverage.
- Due to lack of digital stations in certain regions, some of the stations proposed to cover the seismically active regions are today analog stations (code EA in the table). These stations will need to be upgraded to comply with IMS standards.

## Features of the 130-Station Design

- Relative to the 100 -station design, stations have been added to improve the azimuthal coverage, and also to further improve the coverage of the seismicity zones. The coverage is especially improved in ocean areas by the addition of island stations. Some stations have also been added for better backup, in the sense discussed earlier.
- The event location uncertainties are further reduced (relative to those of the 100 -station network), and nearly all of the landmasses are now inside the $1000 \mathrm{~km}^{2}$ location uncertainty area contours, as shown in Fig. 7.5.2. Again, due care must be exercised in interpreting the simulation results.
- The average octant coverage for this design is above 5 globally.
- The WGE work has shown that the 150 -station design has better performance than the 130 -station design, but the improvements can be termed marginal, and thus perhaps not cost-effective.

## Concluding Remarks

This paper has presented two options for an IMS auxiliary seismic network. Together with material that will be presented by others, this might facilitate the discussions in the GSE.

The question of redundancy in the auxiliary station network has not been considered explicitly in our work. Such redundancy might be needed to secure high data availability from all regions of the world.

The synergy with the hydroacoustic component of IMS has not been assessed quantitatively in this paper. It is expected that such synergy effects will be addressed in the expert meetings after the GSE meeting. Joint work by seismic and hydroacoustic experts may justify omitting some of the island stations from the 130 -station design proposed in this paper.

Further work and discussion are needed to establish the exact locational capability of the networks and the operational status for the existing auxiliary stations proposed in this paper, and to check the progress of plans and proposals for the stations with status "PL" and "PR", respectively, in the table. Further work is also needed to estimate the costs related to bringing stations and communications arrangements in line with the required IMS standards.

Table 7.5.1. The table gives details on the 130 stations proposed for the IMS auxiliary network. The meaning of the colums "Rationale" and "Status" is explained in the text. The rightmost column labelled "100" identifies stations of an optimum 100-station subgroup of this 130station network.

### 7.6 Magnitude estimation at the IDC - a case study

## Introduction

Several recent papers have addressed the shortcomings of the currently available magnitude scales for the purposes of GSETT-3. Harjes (1995) has suggested that a "unified" magnitude scale should be developed for operational use at the IDC. Such a magnitude scale should have the following general characteristics:

- Consistent with current teleseismic $\mathrm{m}_{\mathrm{b}}$
- Applicable to "all" distance ranges
- Computed automatically
- Valid over large magnitude range (at least 2.0-6.5)

The primary purpose would be to develop a "generic" magnitude scale that could be used as a first estimate of $m_{b}$. Subsequent refinements would then be possible by introducing station/region-specific correction factors in areas where adequate data are available.

In the NORSAR Semiannual Technical Summary 1 October 94-31 March 95 Kværna and Ringdal (1995) described a possible approach to developing a unified magnitude scale, by using the IDC Threshold Monitoring system.

By analyzing selected IDC-reported events in detail, they found that the TM approach offers a consistent, automatically computed data set that is directly applicable to $\mathrm{m}_{\mathrm{b}}$ estimation. Since upper limits on all non-detecting stations are provided, the method is easily expandable to include maximum-likelihood magnitude estimates. It was also pointed out that a similar approach can be used to estimate $\mathrm{M}_{\mathrm{S}}$, with upper $90 \% \mathrm{M}_{\mathrm{S}}$ limits provided automatically for events for which no surface waves are detected.

In this paper we follow up the general question of IDC magnitude estimation by analyzing a recent earthquake sequence in Greece during May-June 1995. This includes comparisons of IDC magnitudes in the Reviewed Event Bulletins to those of NORSAR and NEIC, with special view to network bias, recurrence statistics and detectability.

## The Greece earthquake sequence May/June 1995

Several hundred earthquakes from the Greece area were recorded at the NORSAR array during May/June 1995. An example of a 12 -hour period from the NORSAR monthly bulletin is given in Fig. 7.6.1. Many of these events were also listed in the IDC Reviewed Event Bulletin, using mostly the arrays in central/northern Europe as key stations in the location procedure. Fig. 7.6 .2 shows epicenters for a two-week period as given in the biweekly IDC Performance Reports.

As can be seen from Fig. 7.6.1, the majority of the earthquakes were around $m_{b}=4.0$ and lower, thus giving a good basis both for a detectability study and to investigate possible
magnitude bias effects. As is well known (e.g., Ringdal, 1976), a network magnitude bias can be expected at low magnitudes unless maximum-likelihood techniques are applied.

## Magnitude comparisons

Fig. 7.6.3 compares reported magnitudes from the three sources: NORSAR bulletin, IDC REB and NEIC PDE. The following observations are made:

- From plot a) we note that NORSAR and PDE magnitudes are consistent for the larger events, but there is a significant positive "network bias" in the PDE magnitudes for the smaller events. Once the NORSAR magnitude goes below 4.0, the PDE magnitude stays between 4.0 and 4.5 , thus reflecting that only those stations with the highest amplitudes contribute to the average $\mathrm{m}_{\mathrm{b}}$.
- From plot b) we note that there is a bias also in the IDC magnitudes for the smaller events, although this plot has much more scatter than plot a).
- From plot c) we note that IDC magnitudes have a negative bias relative to PDE magnitudes. This is not surprising, and has been documented in many IDC Performance Reports. One possible reason is the dominance of high-frequency arrays in the IDC network. However, the large scatter between IDC and PDE magnitudes is a source of concern, and must be due to other reasons as well. It appears that the automatic algorithm at the IDC for magnitude computation needs significant improvement.

## Recurrence statistics

Fig. 7.6.4 shows cumulative recurrence statistics for NORSAR and REB for the Greece sequence. The slope of the NORSAR plot is close to 1.0 , whereas the REB slope is much steeper. The tendency of REB recurrence curves to show a slope significantly steeper than 1.0 has been observed in many IDC Performance Reports (see e.g. Fig. 7.6.5), and again we prescribe this to a network bias.

It might be noted that under the assumptions of a normal magnitude distribution and an exponential magnitude-frequency relationship ( $\log \mathrm{N}=a \mathrm{~b} * \mathrm{~m}$ ), a single station or array will provide an unbiased estimate of the $b$-value (Ringdal, 1975). On the other hand, the avalue from a single-station or array will be biased due to station bias and station scatter. Therefore the $b$-value of approximately 1.0 inferred from the NORSAR plot should be close to the "real" b-value for this earthquake sequence. When maximum-likelihood magnitudes are implemented at the IDC, we would thus expect the recurrence slopes to become close to 1.0 .

## Detectability

Fig. 7.6.6 shows the estimated incremental detectability of the REB using NORSAR as a reference for the area and time period mentioned. Since NORSAR is currently not participating in GSETT-3, it can reasonably be used as an independent reference system for such
an estimation. The $90 \%$ threshold is close to 4.2 , which is in fact quite similar to the estimate inferred from the theoretical capability plots in the IDC Performance Reports. This consistency is encouraging.

Fig. 7.6.4. Magnitude recurrence statistics for a) NORSAR and b) IDC for six weeks of the Greece earthquake sequence. The straight lines have a slope of 1.0. Note that the NORSAR slope is close to 1.0, whereas the IDC slope appears to be significantly steeper.

Fig. 7.6.5. Recurrence distribution of body-wave ( $m_{b}$ ) and local (ML) magnitudes in the REB for selected regions, as taken from an IDC Performance Report. The stippled lines have a slope of 1.0. Note that the $m_{b}$ recurrence curves have slopes significantly greater than 1.0 for all regions, which is ascribed to a network $m_{b}$ estimation bias.

Fig. 7.6.6. Detectability estimate for the IDC REB for the Greece area using the NORSAR bulletin as a reference. The $90 \%$ detection threshold is $m_{b}=4.2$, which is close to the theoretical estimate in the IDC Performance Reports.

### 7.7 An assessment of the estimated mean mislocation vectors for small-aperture arrays

## Introduction

The objective of this study was to test the applicability of the estimated mean mislocation vectors for small-aperture arrays (Schweitzer, 1994; Schweitzer \& Kværna, 1995) for use with different event-location procedures. The mean mislocation vectors were calculated in the slowness space and are now available for automatically estimated fk-results over a large range of azimuth and ray-parameter values. Additionally, mean standard deviations for the mislocation vectors could be defined as a function of the measured slowness values. All this information can now be used to increase the stability and quality of both phase association and event location based on automatically estimated fk -results.

## Single-array locations

For the four arrays, ARCESS, FINESS, GERESS and NORESS, the data base of slowness correction vectors was sufficiently dense that these corrections could be applied for locating local and regional seismic events. In this way, the correction vectors could be used to improve the single-array locations.

The single-array location procedure RONAPP (Mykkeltveit \& Bungum, 1984) uses the TTAZLOC algorithm (Bratt \& Bache, 1988) and locates events with travel time and azimuth information as input data. Apparent velocities of the detected onsets are only used to identify the different seismic phases. The uncertainties of the estimated parameters (onset time, azimuth and apparent velocity) were calculated from the SNR and the quality of the fk -analysis. Therefore, correcting automatically estimated fk -results with mean mislocation vectors mainly influences the location algorithm in changing the azimuth of the observed phases. Only in some cases does correcting the apparent velocities lead to a change of the estimated phase type (and thereby also a shift to another travel-time table). The standard deviations of the mean mislocation vectors were not taken into account in this study.

To assess the mean mislocation vectors for the four arrays mentioned above, the whole data set for 1994 was reprocessed. Fig. 7.7.1 shows all 25,612 events defined and located by the four small-aperture arrays in the original single-array data analysis. The map clearly shows the concentration of the seismicity at known source regions. Additionally, we can see a more scattered distribution of events located at larger distances from the arrays. The two circles of events around NORESS and ARCESS are an unexplained artefact of the RONAPP recipes for these two arrays.

Fig. 7.7.2 shows the 24,946 relocated events after correcting the automatically estimated slowness values (phase velocity and azimuth) with the mean mislocation vectors. For the phases where a mislocation vector was unassociable, the original slowness values remained unchanged. The reduction of the number of defined and located seismic events by about $2.5 \%$ is mostly caused by a reduction of events far away from the arrays (to see
the reduced number of artificial events scattered in the background, compare with Fig. 7.7.1).

Because most of the events located by the regional arrays are due to man-made activity, this large number of relocated events cannot be compared with independent bulletins. Therefore an evaluation of the results can only be done in a more qualitative way. It is clearly seen that the concentration of events around known source regions in Europe is much higher after introducing the slowness corrections. Especially the azimuthal scatter is smaller. This clearly shows the positive effect of correcting the observed apparent velocities and azimuth values with mean mislocation vectors.

## Slowness residuals in the REBs

After 10 months of operating GSETT-3, the Reviewed Event Bulletins (REBs) contain a huge amount of (automatically) estimated ray parameter and azimuth values observed for the small-aperture arrays ARCESS, FINESS, GERESS and NORESS. Although these values are not always used in the final location of seismic events, ray parameter and azimuth play an important role during the identification and association process at the IDC. It is known that the single ray parameter and azimuth observation of a small-aperture array show a relatively large scatter and additionally often a systematic mislocation. For seismic events with only a few well-defined observations, this scatter will influence the starting location of the event location procedure. In addition, the phase association process will be influenced by the systematic array mislocations. Estimating mean mislocation vectors is part of a needed calibration of all GSETT-3 stations (Harjes et al, 1994). In this study such mean mislocation vectors were tested for application at the IDC.

All REB-events (1 Jan - 31 Oct 1995) located with at least 10 defining phases were investigated for onsets of the four small-aperture arrays. These events were assumed to have a location precision that allowed for investigation of slowness residuals. The ray parameter and azimuth residuals were transformed in a slowness-error vector. Whenever this vector was smaller than $6 \mathrm{sec}{ }^{\circ}$ and the travel time residual of the onset was smaller than 6 sec , this onset was defined as a valid association and the slowness vector was corrected with the mean mislocation vector. Fig. 7.7.3 shows the results for each investigated array. The blue line always shows the distribution of the slowness errors without any correction and the red line shows the distribution of the slowness errors after applying the corrections. The two distributions are normalized relative to the maximum of the occurring slowness errors. The corrected slowness values clearly show smaller errors and should therefore be used in the data processing at the IDC (see Table 7.7.1).
