# Semiannual Technical Summary 

## 1 October 1996-31 March 1997

Kjeller, May 1997

#### Abstract

(cont.) The NORSAR Detection Processing system has been operated throughout the period with an average uptime of $99.89 \%$. A total of 1886 seismic events have been reported in the NORSAR monthly seismic bulletin for October 1996-March 1997. The performance of the continuous alarm system and the automatic bulletin transfer to AFTAC has been satisfactory. Processing of requests for full NORSAR and regional array data on magnetic tapes has progressed according to established schedules.

This Semiannual Report also presents statistics from operation of the Regional Monitoring System (RMS). The RMS has been operated in a limited capacity, with continuous automatic detection and location and with analyst review of selected events of interest for GSETT-3. Data sources for the RMS have comprised all the regional arrays processed at NORSAR. The Generalized Beamforming (GBF) program is now used as a pre-processor to RMS.

On-line detection processing and data recording at the NORSAR Data Processing Center (NDPC) of NORESS, ARCESS, FINESS and GERESS data have been conducted throughout the period. Data from two small-aperture arrays at sites in Spitsbergen and Apatity, Kola Peninsula, as well as the Hagfors array in Sweden, have also been recorded and processed. Monthly processing statistics for the arrays as well as results of the RMS analysis for the reporting period are given.

Maintenance activities in the period comprise preventive/corrective maintenance in connection with all the NORSAR subarrays, NORESS and ARCESS. Other activities have involved repair of defective electronic equipment after thunderstorms in the array area, cable splicing and work in connection with the small-aperture array in Spitsbergen.

Summaries of five scientific contributions are presented in Chapter 7 of this report.
Section 7.1 summarizes the activities related to the GSETT-3 experiment and experience gained at the Norwegian NDC during the period 1 October 1996-31 March 1997. Norway has been contributing primary station data from three arrays: ARCESS, NORESS and NORSAR. NORESS has been a temporary substitute for the large-aperture NORSAR array, awaiting full integration of the NORSAR data in the IDC processing. Norway's NDC is also acting as a regional data center, forwarding data to the IDC from GSETT-3 primary stations in several countries. These currently include FINESS (Finland), GERESS (Germany), and Sonseca (Spain). In addition, communications for the GSETT-3 auxiliary station at Nilore, Pakistan, are provided through a VSAT satellite link between Norway's NDC and Pakistan's NDC in Nilore. Data from the Hagfors array in Sweden, a GSETT-3 auxiliary station, are also provided through Norway's NDC.

The work at the Norwegian NDC has continued to focus on operational aspects, like stable forwarding of data using the Alpha protocol, proper handling of outgoing and incoming messages, improvement to routines for dealing with failure of critical components, as well as implementation of other measures to ensure maximum reliability and robustness in providing data to the IDC. We will continue the efforts towards improvements and hardening of all critical data acquisition and data forwarding hardware and software components, so that requirements now

established by the PrepCom related to operation of IMS stations can be met to the maximum extent possible.

Section 7.2 describes our initial plans for implementing IMS stations in Norway. Six such stations are located on Norwegian territory: Two primary seismic stations (NORSAR and ARCESS), two auxiliary seismic stations (Spitsbergen and Jan Mayen), one planned infrasound array (Karasjok) and one planned radionuclide monitoring station (Spitsbergen).

The four seismic stations listed above are currently operating, and, with the exception of Jan Mayen, are already contributing data to the prototype IDC. The paper specifies the necessary upgrades (mostly of a minor nature) necessary to meet IMS specifications for these stations. NORSAR will function as a Norwegian National Data Center for all the six IMS stations, and will coordinate the necessary upgrades and new establishments with the CTBTO Provisional Technical Secretariat.

Section 7.3 describes the current status of NORSAR large array operation at the IDC testbed, and gives a comparison of results obtained at the IDC with those obtained during local data processing at NORSAR. It appears that the current DFX processing at the IDC is close to satisfactory, although some improvements are needed to correct a problem with some missed detections. Azimuths computed by the DFX algorithm are excellent. Only one process ("Beamer") now remains to be modified at the IDC to handle large-array data. When this is done, everything will be ready for implementing NORSAR large-array processing at the prototype IDC.

Section 7.4 discusses event magnitudes, capability maps and magnitude thresholds. We have developed an algorithm for obtaining short-term average (STA) based magnitude estimates for all Alpha stations in the current GSETT-3 network. This has been done through analysis of a large event data base, where individual relations between A/T and STA were found for each station. Preliminary results show that the STA-based event magnitudes are in close agreement with the event magnitudes provided by the IDC, and that the STA-based station magnitudes have a lower standard deviation than the A/T-based IDC station magnitudes.

By calculating continuous station magnitudes (noise magnitudes), we have developed a simplified algorithm for assessing the three-station network detection capability. During noise conditions these results are in excellent agreement with traditional estimates of the detection capability of the GSETT-3 Alpha network. But unlike the traditional approach, our approach is able to immediately accommodate variations in detection capability caused by "unusual" conditions like station outages, large earthquakes and aftershock sequences, which may cause the network detection capability to deteriorate for hours.

Along the same lines, we use the continuous station magnitudes to compute so-called magnitude threshold maps (threshold monitoring, TM), and we have compared the TM results with those obtained above. During normal noise conditions we find that for the region north of 30 degrees N, the GSETT-3 Alpha network will generally be unable to detect events below $\mathrm{m}_{\mathrm{b}} 3.5$. On the other hand, the TM map tells us that if there was an event in this region, it would need to have a magnitude below 3.0. In somewhat simplified terms, we could say that the TM approach is able to "monitor" and area at an $\mathrm{m}_{\mathrm{b}}$ level 0.5 units lower than the conventional "detection-
based" approach. During the occurrence of large earthquakes, we show that this difference in monitoring performance can become even larger.

Section 7.5 contains a study of seismic travel-time models for the Barents region. As is well known, accurate location of seismic events with a regional network requires detailed knowledge of the propagation characteristics of seismic waves in the region. For Fennoscandia, an excellent velocity model (the NORSAR model) has previously been developed. In this study, we have applied the NORSAR model to the general Barents region, including western Russia, and compared it with the IASPEI-91 model, which is currently used by the prototype IDC.

We have selected six well-recorded events in the region and recomputed the locations using available stations in the GSETT-3 network, the Kola network and the IRIS network. In order to minimize the effect of unknown velocity structure, we have used only P-readings in the relocation procedure. This method is less sensitive to regional variations than using a combination of $P$ and $S$, because a shift in P-velocities will cause a shift in origin time, without influencing significantly the epicentral estimate. In fact, the IASPEI-91 model and the NORSAR model give almost identical location estimates when using P-waves only.

After locating the events, we have compared predicted and actual P and S wave travel times, using both models. Our approach has been, for each model, to use the estimated epicenter and origin time based on the P-data for that model, and then compare the predicted and observed Sarrivals. It turns out that the IASPEI-91 model gives S-wave velocities that are consistently too low compared to the observed data. On the other hand, the NORSAR model shows excellent fit between the predicted and observed arrivals.

We conclude that the NORSAR model is appropriate not only for Fennoscandia, but for the entire Barents region from Spitsbergen to Novaya Zemlya, and also for northwestern Russia. Use of this model would be expected to improve location accuracy considerably compared to use of IASPEI-91, especially when both $P$ and $S$ phases are used in the location procedure. Nevertheless, we find that in many cases a location estimate based on regional $P$ phases alone is more precise than that obtained using both $P$ and $S$ phases. It thus appears that the timing accuracy of IDC $S$ phases needs to be further investigated.

## 1 Summary

This Semiannual Technical Summary describes the operation, maintenance and research activities at the Norwegian Seismic Array (NORSAR), the Norwegian Regional Seismic Array (NORESS), the Arctic Regional Seismic Array (ARCESS) and the Spitsbergen Regional Array for the period 1 October 1996-31 March 1997. Statistics are also presented for additional seismic stations, which through cooperative agreements with institutions in the host countries provide continuous data to the NORSAR Data Processing Center (NPDC). These stations comprise the Finnish Regional Seismic Array (FINESS), the German Regional Seismic Array (GERESS), the Hagfors array in Sweden and the regional seismic array in Apatity, Russia.

The NORSAR Detection Processing system has been operated throughout the period with an average uptime of $99.89 \%$. A total of 1886 seismic events have been reported in the NORSAR monthly seismic bulletin for October 1996-March 1997. The performance of the continuous alarm system and the automatic bulletin transfer to AFTAC has been satisfactory. Processing of requests for full NORSAR and regional array data on magnetic tapes has progressed according to established schedules.

This Semiannual Report also presents statistics from operation of the Regional Monitoring System (RMS). The RMS has been operated in a limited capacity, with continuous automatic detection and location and with analyst review of selected events of interest for GSETT-3. Data sources for the RMS have comprised all the regional arrays processed at NORSAR. The Generalized Beamforming (GBF) program is now used as a pre-processor to RMS.

On-line detection processing and data recording at the NORSAR Data Processing Center (NDPC) of NORESS, ARCESS, FINESS and GERESS data have been conducted throughout the period. Data from two small-aperture arrays at sites in Spitsbergen and Apatity, Kola Peninsula, as well as the Hagfors array in Sweden, have also been recorded and processed. Monthly processing statistics for the arrays as well as results of the RMS analysis for the reporting period are given.

Maintenance activities in the period comprise preventive/corrective maintenance in connection with all the NORSAR subarrays, NORESS and ARCESS. Other activities have involved repair of defective electronic equipment after thunderstorms in the array area, cable splicing and work in connection with the small-aperture array in Spitsbergen.

Summaries of five scientific contributions are presented in Chapter 7 of this report.
Section 7.1 summarizes the activities related to the GSETT-3 experiment and experience gained at the Norwegian NDC during the period 1 October 1996-31 March 1997. Norway has been contributing primary station data from three arrays: ARCESS, NORESS and NORSAR. NORESS has been a temporary substitute for the large-aperture NORSAR array, awaiting full integration of the NORSAR data in the IDC processing. ## 2 NORSAR Operation

### 2.1 Detection Processor (DP) operation

There have been 4 breaks in the otherwise continuous operation of the NORSAR online system within the current 6 -month reporting interval. The uptime percentage for the period is 99.89 .

Fig. 2.1.1 and the accompanying Table 2.1.1 both show the daily DP downtime for the days between 1 October 1996 and 31 March 1997 The monthly recording times and percentages are given in Table 2.1.2.

The breaks can be grouped as follows:
a) Hardware failure 0
b) Stops related to program work or error 0
c) Hardware maintenance stops 0
d) Power jumps and breaks 0
e) TOD error correction 0
f) Communication lines 4

The total downtime for the period was 4 hours and 57 minutes.

### 2.2 Array Communications

After completion of the NORSAR refurbishment project, the operation of the subarray communication lines has proceeded normally.

For a complete description of the NORSAR refurbishment project, reference is made to Section 4.1 of the NORSAR Semiannual Technical Summary, 1 April- 30 September 1995.

From October 1996 through March 1997, there were no significant communications outages at any of the NORSAR subarrays.

A simplified daily summary of the communications performance for the seven individual subarray lines is summarized, on a month-by-month basis, in Table 2.2.1.

### 2.3 NORSAR Event Detection operation

In Table 2.3.1 some monthly statistics of the Detection and Event Processor operation are given. The table lists the total number of detections (DPX) triggered by the on-line detector, the total number of detections processed by the automatic event processor (EPX) and the total number of events accepted after analyst review (teleseismic phases, core phases and total).

|  | Total <br> DPX | Total <br> EPX | Accepted events |  | Sum | Daily |
| :--- | ---: | ---: | ---: | ---: | ---: | ---: |
|  |  |  | P-phases | Core <br> Phases |  |  |
| Oct 96 | 9025 | 769 | 305 | 53 | 358 | 11.5 |
| Nov 96 | 10854 | 855 | 319 | 49 | 368 | 12.3 |
| Dec 96 | 10349 | 645 | 254 | 50 | 304 | 9.8 |
| Jan 97 | 10783 | 1091 | 207 | 57 | 264 | 8.5 |
| Feb 97 | 10346 | 810 | 185 | 37 | 222 | 7.9 |
| Mar 97 | 10138 | 931 | 297 | 73 | 370 | 11.9 |
|  |  |  | 1567 | 319 | 1886 | 10.3 |

Table 2.3.1. Detection and Event Processor statistics, 1 October 1996-31 March 1997.

## NORSAR Detections

The number of detections (phases) reported by the NORSAR detector during day 275, 1996, through day 090, 1997, was 68,435 , giving an average of 378 detections per processed day ( 181 days processed). Table 2.3 .2 shows daily and hourly distribution of detections for NORSAR.

Table 2.3.2. (Page 3 of 4)

Table 2.3.2. Daily and hourly distribution of NORSAR detections. For each day is shown number of detections within each hour of the day and number of detections for that day. The end statistics give total number of detections distributed for each hour and the total sum of detections during the period. The averages show number of processed days, hourly distribution and average per processed day. (Page 4 of 4 )

## 3 Operation of Regional Arrays

### 3.1 Recording of NORESS data at NDPC, Kjeller

The average recording time was $99.54 \%$ as compared to $89.67 \%$ during the previous reporting period.

Table 3.1.1 lists the main outage times and reasons.

| Date | Time |  |
| :--- | :--- | :--- |
| Cause |  |  |
| 12 Nov | $1912-2043$ | Transmission line failure |
| 14 Nov | $0849-1030$ | Transmission line failure |
| 31 Dec | $0000-1131$ | Problems with leap year |
| 11 Feb | $1319-1349$ | Hardware maintenance |
| 12 Feb | $1300-1453$ | Hardware failure |

Table 3.1.1. Interruptions in recording of NORESS data at NDPC, 1 October 1996-31 March 1997.

Monthly uptimes for the NORESS on-line data recording task, taking into account all factors (field installations, transmissions line, data center operation) affecting this task were as follows:

| October 96 | $:$ | 99.89 |
| :--- | :--- | :--- |
| November | $:$ | 99.40 |
| December | $:$ | 98.89 |
| January 97 | $:$ | 99.99 |
| February | $:$ | 99.59 |
| March | $:$ | 99.97 |

Fig. 3.1.1 shows the uptime for the data recording task, or equivalently, the availability of NORESS data in our tape archive, on a day-by-day basis, for the reporting period.

Fig. 3.1.1. NORESS data recording uptime for October (top), November (middle) and December (bottom) 1996.

Fig. 3.1.1. (cont.) NORESS data recording uptime for January (top), February (middle) and March (bottom) 1997.

### 3.2 Recording of ARCESS data at NDPC, Kjeller

The average recording time was $99.02 \%$ as compared to $98.42 \%$ for the previous reporting period.

Table 3.2.1 lists the main outage times and reasons.

| Date | Time | Cause |
| :--- | ---: | :--- |
| 07 Oct | $1312-1457$ | Transmission failure |
| 21 Nov | $0838-1139$ | Power break Hub |
| 31 Dec | $0000-1139$ | Problems with leap year |
| 01 Jan | $2153-\quad$ | Transmission failure |
| 02 Jan | -0658 |  |
| 10 Mar | $0232-1630$ | Power break Hub |

Table 3.2.1. The main interruptions in recording of ARCESS data at NDPC, 1 October 199631 March 1997.

Monthly uptimes for the ARCESS on-line data recording task, taking into account all factors (field installations, transmissions line, data center operation) affecting this task were as follows:

$$
\begin{array}{lll}
\text { October } 96 & : & 99.74 \% \\
\text { November } & : & 99.57 \% \\
\text { December } & : & 98.10 \% \\
\text { January } 97 & : & 98.76 \% \\
\text { February } & : & 99.90 \% \\
\text { March } & : & 98.07 \%
\end{array}
$$

Fig. 3.2.1. shows the uptime for the data recording task, or equivalently, the availability of ARCESS data in our tape archive, on a day-by-day basis, for the reporting period.

Fig. 3.2.1. ARCESS data recording uptime for October (top), November (middle) and December (bottom) 1996.

Fig. 3.2.1. ARCESS data recording uptime for January (top), February (middle) and March (bottom) 1997

### 3.3 Recording of FINESS data at NDPC, Kjeller

The average recording time was $99.49 \%$ as compared to $98.79 \%$ for the previous reporting period.

| Date | Time |  |
| :--- | :--- | :--- |
| Cause |  |  |
| 12 Oct | $1625-1705$ | Stop in Helsinki |
| 19 Nov | $0953-1054$ | Stop in Helsinki |
| 09 Feb | $0718-0804$ | VSAT/LAN problems in Helsinki |
| 09 Feb | $0950-1530$ | VSAT/LAN problems in Helsinki |
| 11 Mar | $1304-1738$ | Transmission error 3.5 hours lost |
| 13 Mar | $0850-1752$ | Transmission failure in Helsinki |

Table 3.3.1. The main interruptions in recording of FINESS data at NDPC, 1 October 1996 31 March 1997.

Monthly uptimes for the FINESS on-line data recording task, taking into account all factors (field installations, transmission lines, data center operation) affecting this task were as follows:

| October 96 | $:$ | $99.87 \%$ |
| :--- | :--- | :--- |
| November | $:$ | $99.84 \%$ |
| December | $:$ | $99.96 \%$ |
| January 97 | $:$ | $99.96 \%$ |
| February | $:$ | $99.04 \%$ |
| March | $:$ | $98.29 \%$ |

Fig. 3.3.1 shows the uptime for the data recording task, or equivalently, the availability of FINESS data in our tape archive, on a day-by-day basis, for the reporting period.

Fig. 3.3.1. FINESS data recording uptime for October (top), November (middle) and December (bottom) 1996.

Fig. 3.3.1. FINESS data recording uptime for January (top), February (middle) and March (bottom) 1997.

### 3.4 Recording of Spitsbergen data at NDPC, Kjeller

The average recording time was $98.91 \%$ as compared to $96.63 \%$ for the previous reporting period.

The main reasons for downtime follow:

| Date | Time | Cause |
| :---: | :---: | :--- |
| 24 Jan | $2254-$ | Communication link failure |
| 25 Jan | -0922 |  |
| 25 Jan | $1802-2221$ | Communication link failure |
| 25 Jan | $2305-$ | Communication link failure |
| 26 Jan | -0906 |  |
| 06 Feb | $2210-2254$ | Satellite software maintenance |
| 13 Feb | $0321-0806$ | Satellite software maintenance |
| 14 Feb | $0819-0846$ | Hardware maintenance |
| 14 Feb | $0858-0913$ | Hardware maintenance |
| 28 Mar | $0032-0237$ | Communication link failure |

Table 3.4.1. The main interruptions in recording of Spitsbergen data at NDPC, 1 October 1996 - 31 March 1997.

Monthly uptimes for the Spitsbergen online data recording task, taking into account all factors (field installations, transmission line, data center operation) affecting this task were as follows:

| October 96 | $:$ | $99.96 \%$ |
| :--- | :--- | ---: |
| November | $:$ | $100.00 \%$ |
| December | $:$ | $100.00 \%$ |
| January 97 | $:$ | $94.95 \%$ |
| February | $:$ | $99.01 \%$ |
| March | $:$ | $99.55 \%$ |

Fig. 3.4.1 shows the uptime for the data recording task, or equivalently, the availability of Spitsbergen data in our tape archive, on a day-by-day basis for the reporting period.

### 3.5 Event detection operation

This section reports results from one-array automatic processing using signal processing recipes and "ronapp" recipes for the ep program (NORSAR Sci. Rep. No 2-8889).

Three systems are in parallel operation to associate detected phases and locate events:

1. The ep program with "ronapp" recipes is operated independently on each array to obtain simple one-array automatic solutions.
2. The Generalized Beamforming method (GBF) (see F. Ringdal and T. Kværna (1989), A mulitchannel processing approach to real time network detection, phase association and threshold monitoring, BSSA Vol 79, no 6, 1927-1940) processes the four arrays jointly and presents locations of regional events.
3. The RMS system (Regional Monitoring System; previously referred to as the IMS system (Intelligent Monitoring System) system) is operated on the same set of arrivals as ep and GBF and reports also teleseismic events in addition to regional ones.

RMS results are reported in section 3.6.

## NORESS detections

The number of detections (phases) reported from day 275, 1996, through day 090, 1997, was 67,729 , giving an average of 372 detections per processed day ( 182 days processed).

Table 3.5 .1 shows daily and hourly distribution of detections for NORESS.

## Events automatically located by NORESS

During days 275,1996 , through 090, 1997, 2998 local and regional events were located by NORESS, based on automatic association of P- and S-type arrivals. This gives an average of 16.5 events per processed day ( 182 days processed). $45 \%$ of these events are within 300 km , and $79 \%$ of these events are within 1000 km .

## ARCESS detections

The number of detections (phases) reported during day 275,1996 , through day 090,1997 , was 94,437 , giving an average of 519 detections per processed day ( 182 days processed).

Table 3.5.2 shows daily and hourly distribution of detections for ARCESS.

## Events automatically located by ARCESS

During days 275,1996 , through $090,1997,5434$ local and regional events were located by ARCESS, based on automatic association of P- and S-type arrivals. This gives an average of 29.9 events per processed day ( 182 days processed). $46 \%$ of these events are within 300 km , and $81 \%$ of these events are within 1000 km .

## FINESS detections

The number of detections (phases) reported during day 275, 1996, through day 090, 1997, was 47,166 , giving an average of 259 detections per processed day ( 182 days processed).

Table 3.5.3 shows daily and hourly distribution of detections for FINESS.

## Events automatically located by FINESS

During days 275, 1996, through 090, 1997, 2424 local and regional events were located by FINESS, based on automatic association of P- and S-type arrivals. This gives an average of 13.3 events per processed day ( 182 days processed). $80 \%$ of these events are within 300 km , and $92 \%$ of these events are within 1000 km .

## GERESS detections

The number of detections (phases) reported from day 275, 1996, through day 090, 1997, was 33,545 , giving an average of 185 detections per processed day ( 181 days processed).

Table 3.5 .4 shows daily and hourly distribution of detections for GERESS.

## Events automatically located by GERESS

During days 275, 1996, through 090, 1997, 3706 local and regional events were located by GERESS, based on automatic association of P- and S-type arrivals. This gives an average of 20.6 events per processed day ( 180 days processed). $71 \%$ of these events are within 300 km , and $89 \%$ of these events are within 1000 km .

## Apatity array detections

The number of detections (phases) reported from day 275, 1996, through day 090, 1997, was 46,758 , giving an average of 257 detections per processed day ( 182 days processed).

As described in earlier reports, the data from the Apatity array are transferred by one-way (simplex) radio links to Apatity city. The transmission suffers from radio disturbances that occasionally result in a large number of small data gaps and spikes in the data. In order for the communication protocol to correct such errors by requesting retransmission of data, a two-way radio link would be needed (duplex radio). However, it should be noted that noise from cultural activities and from the nearby lakes cause most of the unwanted detections. These unwanted detections are "filtered" in the signal processing, as they give seismic velocities that are outside accepted limits for regional and teleseismic phase velocities.

Table 3.5.5 shows daily and hourly distribution of detections for the Apatity array.

## Events automatically located by the Apatity array

During days 275,1996 , through 090, 1997, 913 local and regional events were located by the Apatity array, based on automatic association of P- and S-type arrivals. This gives an average
of 5.0 events per processed day ( 182 days processed). $45 \%$ of these events are within 300 km , and $71 \%$ of these events are within 1000 km .

## Spitsbergen array detections

The number of detections (phases) reported from day 275, 1996, through day 090, 1997, was 131,713, giving an average of 724 detections per processed day ( 182 days processed).

Table 3.5.6 shows daily and hourly distribution of detections for the Spitsbergen array.

## Events automatically located by the Spitsbergen array

During days 275,1996 , through $090,1997,10,117$ local and regional events were located by the Spitsbergen array, based on automatic association of P- and S-type arrivals. This gives an average of 55.6 events per processed day ( 182 days processed). $50 \%$ of these events are within 300 km , and $75 \%$ of these events are within 1000 km .

## Hagfors array detections

The number of detections (phases) reported from day 275, 1996, through day 090, 1997, was 75,343 , giving an average of 414 detections per processed day ( 182 days processed).

Table 3.5.7 shows daily and hourly distribution of detections for the Hagfors array

## Events automatically located by the Hagfors array

During days 275,1996 , through 090, 1997, 2818 local and regional events were located by the Hagfors array, based on automatic association of P - and S -type arrivals. This gives an average of 15.5 events per processed day ( 183 days processed). $27 \%$ of these events are within 300 km , and $74 \%$ of these events are within 1000 km

Table 3.5.1. (Page 4 of 4) Daily and hourly distribution of NORESS detections. For each day is shown number of detections within each hour of the day, and number of detections for that day. The end statistics give total number of detections distributed for each hour and the total sum of detections during the period. The averages show number of processed days, hourly distribution and average per processed day.

Table 3.5.2 (Page 2 of 4)

ARC . FKX Hourly distribution of detections

Table 3.5.2 (Page 3 of 4)

Table 3.5.2. (Page 4 of 4) Daily and hourly distribution of ARCESS detections. For each day is shown number of detections within each hour of the day, and number of detections for that day. The end statistics give total number of detections distributed for each hour and the total sum of detections during the period. The averages show number of processed days, hourly distribution and average per processed day.

Table 3.5.3. (Page 4 of 4) Daily and hourly distribution of FINESS detections. For each day is shown number of detections within each hour of the day, and number of detections for that day. The end statistics give total number of detections distributed for each hour and the total sum of detections during the period. The averages show number of processed days, hourly distribution and average per processed day.

Table 3.5.4. (Page 4 of 4) Daily and hourly distribution of GERESS detections. For each day is shown number of detections within each hour of the day, and number of detections for that day. The end statistics give total number of detections distributed for each hour and the total sum of detections during the period. The averages show number of processed days, hourly distribution and average per processed day.

Table 3.5.5 (Page 2 of 4)

APA. FRX Hourly distribution of detections

Table 3.5.5 (Page 3 of 4)

Table 3.5.5.(Page 4 of 4) Daily and hourly distribution of Apatity array detections. For each day is shown number of detections within each hour of the day, and number of detections for that day. The end statistics give total number of detections distributed for each hour and the total sum of detections during the period. The averages show number of processed days, hourly distribution and average per processed day

Table 3.5.6 (Page 3 of 4)

Table 3.5.6. (Page 4 of 4) Daily and hourly distribution of Spitsbergen array detections. For each day is shown number of detections within each hour of the day, and number of detections for that day. The end statistics give total number of detections distributed for each hour and the total sum of detections during the period. The averages show number of processed days, hourly distribution and average per processed day.

HFS . FKX Hourly distribution of detections

Table 3.5.7 (Page 3 of 4)

Table 3.5.7. (Page 4 of 4) Daily and hourly distribution of Hagfors array detections. For each day is shown number of detections within each hour of the day, and number of detections for that day. The end statistics give total number of detections distributed for each hour and the total sum of detections during the period. The averages show number of processed days, hourly distribution and average per processed day

### 3.6 Regional Monitoring System operation

The Regional Monitoring System (RMS) was installed at NORSAR in December 1989 and was operated at NORSAR from 1 January 1990 for automatic processing of data from ARCESS and NORESS. A second version of RMS that accepts data from an arbitrary number of arrays and single 3 -component stations was installed at NORSAR in October 1991, and regular operation of the system comprising analysis of data from the 4 arrays ARCESS, NORESS, FINESS and GERESS started on 15 October 1991. As opposed to the first version of RMS, the one in current operation also has the capability of locating events at teleseismic distance.

Data from the Apatity array were included on 14 December 1992, and from the Spitsbergen array on 12 January 1994. Detections from the Hagfors array were available to the analysts and could be added manually during analysis from 6 December 1994. After 2 February 1995, Hagfors detections were also used in the automatic phase association.

The operational stability of RMS has been very good during the reporting period. In fact the RMS event processor (pipeline) has had no downtime of its own; i.e., all data available to RMS have been processed by RMS.

## Phase and event statistics

Table 3.6.1 gives a summary of phase detections and events declared by RMS. From top to bottom the table gives the total number of detections by the RMS, the number of detections that are associated with events automatically declared by the RMS, the number of detections that are not associated with any events, the number of events automatically declared by the RMS, the total number of events defined by the analyst, and finally the number of events accepted by the analyst without any changes (i.e., from the set of events automatically declared by the RMS).

Due to reductions in the FY94 funding for RMS activities (relative to previous years), new criteria for event analysis were introduced from 1 January 1994. Since that date, only regional events in areas of special interest (e.g, Spitsbergen, since it is necessary to acquire new knowledge in this region) or other significant events (e.g, felt earthquakes and large industrial explosions) were thoroughly analyzed. Teleseismic events were analyzed as before.

To further reduce the workload on the analysts and to focus on regional events in preparation for Gamma-data submission during GSETT-3, a new processing scheme was introduced on 2 February 1995. The GBF (Generalized Beamforming) program is used as a pre-processor to RMS, and only phases associated to selected events in northern Europe are considered in the automatic RMS phase association. All detections, however, are still available to the analysts and can be added manually during analysis.

There is one exception to the new rule for automatic phase association: all detections from the Spitsbergen array are passed directly on to the RMS. This allows for thorough analysis of all events in the Spitsbergen region.

|  | Oct 96 | Nov 96 | Dec 96 | Jan 97 | Feb 97 | Mar 97 | Total |
| :--- | ---: | ---: | ---: | ---: | ---: | ---: | ---: |

## 4 Improvements and Modifications

### 4.1 NORSAR

## NORSAR instrumentation

Within each of the NORSAR subarrays, the remote sensors are all connected to a central hub through buried cables. This system of cables acts like an antenna for lightning, and the first summer of operation showed that the high sensitivity of the new components gave increased problems with lightning.

However, the installed protection system has successfully protected the digitizer, so that only 8 AIM24 digitizers have been damaged, but all were repaired by NMC personnel. On the other hand, about 30 Brick amplifiers have been destroyed due to lightning.

Another result of the lightning has been spikes across the array. This was reported in NORSAR Sci. rep. 2-95/96 as an unidentified artificial signal. It is now clear that the signals are caused by lightning.

During this reporting period, 8 AIM24 digitizers, 30 Brick amplifiers and 1 KS54000P have been repaired and reinstalled. A lot of experimentation and design has been carried out to isolate the lightning problem. A galvanic shield has been designed and will be installed this summer that will both give more protection and reduce the problem with spikes.

A block diagram of the remote sensor site components is found in NORSAR Sci. Rep. No. 195/96.

## NORSAR data acquisition

The Science Horizons XAVE data acquisition system has been operating satisfactorily during the reporting period. A block diagram of the digitizer and communication controller components is found in NORSAR Sci. Rep No 2-94/95.

## NORSAR detection processing and feature extraction

The NORSAR detection processor has been running satisfactorily. To maintain consistent detection capability, the NORSAR beam tables have remained unchanged.

Detection statistics for the NORSAR array are given in section 2.
The NORSAR detecting beams include slowness vector and time delay corrections using precalculated, calibrated time delays.

See NORSAR Sci. Rep. 2-95/96 for a description of NORSAR beamforming techniques.

## NORSAR event processing

The automatic routine processing of NORSAR events as described in NORSAR Sci. Rep. No. 2-93/94, has been running satisfactorily. The analyst tools for reviewing and updating the solutions have been continuously modified to simplify operations and improve results.
J. Fyen

## 5 Maintenance Activities

## Activities in the field and at the Maintenance Center

This section summarizes the activities at the Maintenance Center (NMC) Hamar, and includes activities related to monitoring and control of the NORSAR teleseismic array, as well as the NORESS, ARCESS, FINESS, GERESS, Apatity, Spitsbergen and Hagfors small-aperture arrays.

Activities also involve preventive and corrective maintenance, planning and activities related to the refurbishment of the NORSAR teleseismic array.

## NORSAR

Visits to subarrays in connection with:

- Cable splicing
- Replacement of AlM-24 digitizers and preamplifiers
- Replacement of modems at remote sites
- Removal of broadband seismometers damaged by lightning

## NORESS

- Repair of fiber optical cards
- Replacement of battery bank in the UPS unit in the hub

## Spitsbergen

- Inspection visit to the array

NMC

- Repair of defective electronic equipment

Additional details for the reporting period are provided in Table 5.1.

## 7 Summary of Technical Reports / Papers Published

### 7.1 Status Report: Norway's participation in GSETT-3

## Introduction

This contribution is essentially an update of the two status reports Mykkeltveit \& Baadshaug (1996a) and Mykkeltveit \& Baadshaug (1996b) which cover the periods January 1995 - June 1996 and April 1996 - September 1996, respectively.

## Norwegian GSETT-3 stations and communications arrangements

From the second half of 1993 until 1 October 1996, Norway provided continuous data from three GSETT-3 primary array stations: ARCESS, NORESS and Spitsbergen. The location and configurations of these three stations are shown in Fig. 7.1.1. ARCESS and NORESS are 25element arrays with identical geometries and an aperture of 3 km , whereas the Spitsbergen array has 9 elements within a $1-\mathrm{km}$ aperture. All three stations have a broadband three-component seismometer at the array center.

Data from these three stations were transmitted continuously and in real time to NOR_NDC. The NORESS data transmission uses a dedicated $64 \mathrm{Kbits} / \mathrm{s}$ land line, whereas data from the other two arrays are transmitted via satellite links of capacity $64 \mathrm{Kbits} / \mathrm{s}$ and $19.2 \mathrm{Kbits} / \mathrm{s}$ for the ARCESS and Spitsbergen arrays, respectively.

The NORESS array has been used in GSETT-3 as a temporary substitute for the NORSAR teleseismic array (also shown in Fig. 7.1.1; station code NOA), awaiting a complete technical refurbishment of the latter. This effort has now been completed, and starting 30 August 1996, data from the NORSAR array have been transmitted continuously to the IDC. The NORESS array will, however, be retained as a GSETT-3 primary station at least until such time that the NORSAR array data are fully used in the IDC operational processing cycle. We are cooperating with the IDC on the task of preparing for the processing of NORSAR data at the IDC (see section 7.3 of this report). Some Testbed processing of NORSAR data has been performed. The purpose of the IDC Testbed is to facilitate integration testing and therefore minimize disruption to the operational system. The Testbed is basically a scaled down version of the operational system.

On 1 October 1996 numerous changes were made worldwide to the GSETT-3 network. The purpose of these coordinated changes was to bring the GSETT-3 network in line with the seismic component of the International Monitoring System (IMS) to the extent possible. As the Spitsbergen array is an auxiliary station in IMS, this station changed its status from primary to auxiliary in GSETT-3 on that date. This involved terminating the continuous forwarding of SPITS data to the IDC and making data from this station available to the IDC on a request basis via the AutoDRM protocol (Kradolfer, 1993; Kradolfer, 1996).

## Uptimes and data availability

Figs. 7.1.2-7.1.4 show the monthly uptimes for the two Norwegian GSETT-3 primary stations ARCESS, NORESS and for the testbed primary station NOA, respectively, for the period October 1996 -March 1997, given as the hatched (taller) bars in these figures. These barplots reflect the percentage of the waveform data that are available in the NOR_NDC tape archives for each of these three stations. The downtimes inferred from these figures thus represent the cumulative effect of field equipment outages, station site to NOR_NDC communication outages and NOR_NDC data acquisition outages.

Figs. 7.1.2-7.1.4 also give the data availability for these three stations as reported by the IDC in the IDC Station Status reports. The main reason for the discrepancies between the NOR_NDC and IDC data availabilities as observed from these figures is the difference in the ways the two data centers report data availability for arrays: Whereas NOR_NDC reports an array station to be up and available if at least one channel produces useful data, the IDC uses weights where the reported availability (capability) is based on the number of actually operating channels. As can be seen from these figures, these differences in the reporting practice in particular affect the results for the NORESS and NOA arrays.

## Experience with the AutoDRM protocol

NOR_NDC's AutoDRM has been operational since November 1995 (Mykkeltveit \& Baadshaug, 1996).

Between November 1995 and the network changes on 1 October 1996, only 207 requests from external users were processed.

After SPITS changed station status from primary to auxiliary, the request load increased sharply, and for the month of October 1996, the NOR_NDC AutoDRM responded to 12338 requests for SPITS waveforms from two different accounts at the IDC: 9555 response messages were sent to the "pipeline" account and 2783 to "testbed".

The monthly number of requests for SPITS data is shown in Fig. 7.1.5.

## NDC automatic processing and data analysis

These tasks have proceeded in accordance with the descriptions given in Mykkeltveit and Baadshaug (1996a). For the period October 1996 - March 1997, NOR_NDC derived information on 1209 supplementary events in northern Europe and submitted this information to the Finnish NDC as the NOR_NDC contribution to the joint Nordic Supplementary (Gamma) Bulletin, which in turn is forwarded to the IDC. These events are plotted in Fig. 7.1.6.

## Data forwarding for GSETT-3 stations in other countries

NOR_NDC continues to forward data to the IDC from GSETT-3 primary stations in several countries. These currently include FINESS (Finland), GERESS (Germany) and Sonseca (Spain). In addition, communications for the GSETT-3 auxiliary station at Nilore, Pakistan, are provided through a VSAT satellite link between NOR_NDC and Pakistan's NDC in Nilore. Data from the Hagfors array (HFS) in Sweden were provided continuously through

NOR_NDC until 1 October 1996, on which date this station changed its status in GSETT-3 from primary to auxiliary, in accordance with the status of HFS in IMS. From 1 October 1996, the IDC obtains HFS data through requests to the AutoDRM server at NOR_NDC (in the same way requests for Spitsbergen array data are now handled, see above). Fig. 7.1.7 shows the monthly number of requests for HFS data from the two IDC accounts "pipeline" and "testbed".

## Future plans

NOR_NDC will continue the efforts towards improvements and hardening of all critical data acquisition and data forwarding hardware and software components, so as to meet requirements related to operation of IMS stations to the maximum extent possible. For example, the PrepCom (Preparatory Commission for the Comprehensive Nuclear Test-Ban Organization) has now adopted a data availability of $98 \%$ or more as a requirement for primary and auxiliary IMS seismic stations. Figs. 7.1.2-4 show that this requirement is met for the three primary stations ARCES, NORES and NOA, as far as availability at NOR_NDC is concerned.

The PrepCom has now tasked its Working Group B with overseeing the GSETT-3 experiment until the end of 1997, and to submit proposals to the PrepCom on the basis for the continuation of GSETT-3 in 1998. Whatever this basis will be, we envisage continuing the provision of data from Norwegian IMS stations without interruption to the prottype IDC in Arlington, Virginia, USA and later on to the IDC in Vienna, following the installation of the new global communications infrastructure now envisaged by the PrepCom.

### 7.2 Initial plans for implementing IMS stations in Norway

## Introduction

Annex 1 to the protocol to the Comprehensive Nuclear Test-Ban Treaty contains tables listing altogether 321 stations in the International Monitoring System (IMS) that will be installed to verify compliance with the treaty. Six of these stations are located on Norwegian territory. These stations are listed in Table 7.2.1 and shown in Fig. 7.2.1.

Work is now underway under the direction of PrepCom (Preparatory Commission for the Comprehensive Nuclear Test-Ban Treaty Organization) and its Provisional Technical Secretariat (PTS) in Vienna to establish the IMS. For example, technical specifications for the various sensor types of the IMS have been approved by PrepCom, and a budget for 1997 for site surveying and station upgrading/installation has been adopted. Discussions on the continuation of this installation program in 1998 have already started in PrepCom.

In our capacity of National Data Center for Norway, NORSAR will be technically responsible for the operation and maintenance of IMS stations on Norwegian territory. NORSAR is therefore prepared to cooperate with the PTS in the conduct of site surveys and IMS stations upgrading/installation, and this short paper presents our current thinking in terms of initial plans for implementation of the six IMS stations in Norway.

## Initial plans for each of the six IMS stations in Norway

## The NORSAR large-aperture seismic array

This IMS primary seismic station has recently undergone a comprehensive refurbishment program and basically meets the requirements for technical station specifications (with the exception that data are currently not authenticated) now adopted by the PrepCom (see PrepCom document CTBT/PC/II/1/Add.2). There is, however, still need for some future work, as detailed in the following:

- There is a need to further harden the field installations to secure long-term maintainability. This can partly be achieved through measures to make certain hardware components less vulnerable to external loading, like electrical interferences. The NORSAR array is located in an area that is exposed to frequent lightning strikes during the summer season (May-September).
- As mentioned above, the NORSAR array was recently refurbished. The version of AIM digitizers installed are, however, no longer produced by the manufacturer (Science Horizons). The implications of this in terms of long-term maintainability must be investigated.
- The NORSAR array has currently no on-site data buffering capability (with the exception of a buffer of a few hours' length between the digitizers and communication interface modules). Such a capability is essential in ensuring data continuity in cases of communications line dropouts as well as problems at the data receive end (national or international data center). It is therefore planned that such a capability will be installed.
- We intend to furnish the NORSAR array with a regional processing capability through the integration of the co-located NORESS regional array. The NORESS electronics equipment will need to be replaced before a full integration can take place.

## The ARCESS seismic array

This array has been selected as an IMS primary seismic station. It was installed in 1987 and uses technology designed and developed by the Sandia National Laboratory in Albuquerque, New Mexico, USA, in the early 1980s.

Strictly speaking, the ARCESS array nominally satisfies the minimum IMS station requirements, again with the exception that there are currently no data authentication arrangements. With the exception of the seismometers, however, the array electronic components are the only ones of their kind in the world, and it will thus not be possible to maintain this array when the present supply of spares is exhausted. So there is a definite need to replace the array data acquisition system (mainly digitizers, clocks and "array controller") with standardized equipment that will be maintainable in the forseeable future. The current ARCESS system has no on-site data buffering, and for the same reasons as given above for the NORSAR array, we plan to install such a capability.

## The Spitsbergen seismic array

The existing seismic array at Spitsbergen was selected as one of the 120 IMS auxiliary seismic stations. This array was built in 1992 and is located in a very challenging Arctic environment. For example, the supply of power to the field installation is through the use of windmills that charge a battery bank. After some considerable efforts in identifying the best windmill technology and optimum batteries for this environment, the power supply for the Spitsbergen field system has lately been very stable. There is, however, a need to strengthen this system by installing another windmill so that the station will operate even in case of failure of one of the windmills.

The data from the various sensor sites of the Spitsbergen array are transmitted in analog form via buried cables (of lengths up to 1 km ) to digitizers located at the array center. This limits the dynamic range of the data, and there is a need to install digitizers as well as GPS clocks at each sensor location. There is also a need to provide more state-of-health information than is done today from this station.

The data from the Spitsbergen array digitizers are transmitted via one-way radio links to the array controller, which is located in Longyearbyen at a distance of approximately 18 km from the array site. There is a need for a two-way radio link to support the sending of commands (e.g., calibration commands) to the field equipment.

After completion of the modifications to the Spitsbergen array indicated above, we are confident that this array will fully satisfy the requirements adopted by PrepCom.

## The Jan Mayen seismic station

Since 1962 the University of Bergen, Norway, has operated seismic stations on the small Norwegian island of Jan Mayen situated on the mid-Atlantic ridge. There is currently a broad-band

3-component station at Jan Mayen, and this station was selected as one of the IMS auxiliary stations. We have been in contact with the University of Bergen regarding the technical status of the existing station at Jan Mayen. The seismometer used today is of type Streckeisen STS-2, which is fully adequate for the IMS. It is our assessment, however, that the digitizer and on-site data-buffering equipment need to be replaced.

We are also discussing with the University of Bergen how to arrange communications for this station. The Jan Mayen island has a satellite system today that handles communications to and from mainland Norway. It is considered to be cost-effective and also optimal with respect to future maintenance to integrate the Jan Mayen seismic station communications with the existing communications infrastructure.

## The infrasound station at Karasjok

This IMS station does not exist today and will be built at the location of the ARCESS primary seismic station. This co-location with the ARCESS array will be cost-efficient, as the communications infrastructure for the ARCESS seismic array can then also be used for the infrasound data.

The PrepCom has allocated funds for a site survey in 1997 for this infrasound station. It is our intention to closely cooperate with the PTS in the conduct of this site survey and possibly also involve Norwegian expertise outside NORSAR. The standard IMS infrasound stations are planned to be four-element arrays (triangle with a fourth element in the center) of aperture 1-3 km . The site survey will need to determine suitable locations of each of the sensors (microbarographs) with its noise-reducing pipes or hoses, taking into account the effects of terrain, wind and local vegetation.

## The radionuclide station at Spitsbergen

The geographical coordinates proposed for this yet-to-be-built IMS station are the same as those of the Spitsbergen auxiliary seismic station. In practice, we consider that an optimum location for this new station will be in Longyearbyen (a small settlement with about 1000 inhabitants), at a distance of 15 km from the seismic station. The radionuclide station could possibly be located in the vicinity of the location of the Spitsbergen array controller in Longyearbyen, and thus make use of the communications infrastructure already established for transmission of the seismic data.

Work is now underway in PrepCom to try to reach agreement on which 40 out of the 80 IMS radionuclide stations that will be capable of noble gas monitoring (in addition to the particulate monitoring) upon entry into force of the treaty. We thus anticipate a decision by PrepCom, hopefully in September this year, whether the Spitsbergen radionuclide station should be planned to have a noble gas detection capability in its initial configuration or not.

As we have no expertise of our own at NORSAR within the field of radionuclide monitoring, we are consulting with experts of the Norwegian Radiation Protection Authority (in Norwegian: Statens Strålevern) on matters related to this new station. Nevertheless, NORSAR will function as a coordinating agency in this regard, and will be the point of contact for the PTS in the future establishment and operation of this station.

## Communications

PrepCom's Working Group B is currently working on a design of the future global communications infrastructure that will be established to support a) the transmission of data from the 321 IMS stations to the IDC, and b) the forwarding of data and products from the IDC to the State Signatories. This work will need to be concluded before it will be clear in detail how communications will be arranged for the Norwegian IMS stations. But irrespective of how this will be handled, NORSAR will need to receive data directly from these stations, in order to adequately carry out our tasks in operating and maintaining the six Norwegian IMS stations.

The NORSAR array requires one communication line from each of the 7 concentrated regions of instrumentation of the array (the so-called subarrays). Maintaining the current communications infrastructure with 7 domestic links to the Norwegian NDC and one international link to the IDC would be expected to reduce the overall cost for communications in the future IMS. In addition, the buffering at the NDC ensures high data availability and eases the system monitoring and maintenance functions performed by the NDC. The use of ten domestic VSAT links ( 7 for the NORSAR array, one for Karasjok, one for Jan Mayen and one for Spitsbergen) and one well-monitored high-speed international link may well prove to be the most reliable and costeffective arrangement in the future for Norway's six IMS stations.

## S. Mykkeltveit

J. Fyen

Table 7.2.1. IMS stations located on Norwegian territory, and listed in the protocol to the Comprehensive Nuclear Test-Ban Treaty.

| IMS Network | Station | Lattude | Longitude |
| :---: | :---: | :---: | :---: |
| Seismic primary | NORSAR array, NAO Hamar | 60.8 N | 10.8 E |
| Seismic primary | ARCESS array, ARAO Karasjok | 69.5 N | 25.5 E |
| Seismic auxiliary | Spitsbergen array, SPITS Spitsbergen | 78.2 N | 16.4 E |
| Seismic auxiliary | 3-C station, JMI <br> Jan Mayen | 70.9 N | 8.7W |
| Infrasound | Karasjok | 69.5 N | 25.5 E |
| Radionuclide | Spitsbergen | 78.2 N | 16.4 E |

Fig. 7.2.1. The figure shows the six IMS stations located on Norwegian territory.

### 7.3 NORSAR Large Array Processing at the IDC Testbed

## Introduction

Beginning 1 September 1996, the large array NORSAR (NOA) data have been continuously transmitted to the IDC. Already in April 1996, a new function, "compute-beamform-fk" (Fyen 1996), to be used for large array slowness vector estimation, was implemented into the DFX in cooperation with SAIC staff.

IDC testbed operation of this version for NOA data was initiated on 9 October 1996.

## DFX processing at the testbed

During the period 11 January 1997 through 19 February 1997, we analyzed carefully the results from IDC REB, the NOA detection processing done at NDPC, and the NOA testbed DFX processing done at the IDC.

Using an automated process, we calculated for each REB event the predicted arrival time and back-azimuth for NORES and NOA. If a detection was found with onset time within the expected IASPEI arrival time $+/-5.0$ seconds, then the detection was declared as belonging to the event. If the detection in addition had an azimuth within $+/-15.0$ degrees, then the detection was associated to the event. For simplicity, only P, PKiKP, PKPdf and PKPbc (depending on distance) were used to predict arrival time. Only events in the teleseismic range, i.e., more than 20.0 degrees from NOA were analyzed.

Table 7.3.1 summarizes our findings.
In the table, the term "detection" is used to describe the number of REB events for which at least one detection had an onset time within the predicted arrival time $+/-5.0$ seconds. The term "association" is used to describe the number of REB events for which at least one detection had both onset time within the predicted arrival time window and azimuth within the predicted back-azimuth $+/-15.0$ degrees.

The term "NORSAR" is used to define the number of events for which either NDPC processing or DFX testbed processing detected with NOA array data. "DFX testbed NOA" means detections obtained by DFX processing. "NDPC" means detections obtained with the old detection processing (DP/EP) done at NDPC. NORES detection or association is based on REB origin, assoc and arrival tables from the IDC operations database.

The interpretation of the results is that DFX has fewer detections that can be associated with events as compared to the original NDPC processing. We have from earlier studies found that the individual processing of 10 -minute segments may cause some boundary problems, and this could explain some of the difference. Moreover, the time delays across the NORSAR array are up to 9 seconds, and reduction from triggers to detections is more complicated than for smaller arrays. Several case studies have been performed to select parameters for this process, but more work needs to be done.

Table 7.3.1. Detection statistics 11 January - 19 February 1997. See text for explanation.

|  | Number of events |
| :---: | :---: |
| Number of teleseismic events in REB | 1911 |
| No NORES or NORSAR detection | 1296 |
| Either NORES or NORSAR detection | 615 |
| Either NORES association or NORSAR association | 453 |
| NORES association, but no NORSAR association | 117 |
| NORSAR association, but no NORES association | 129 |
| NORSAR and NORES association | 207 |
| NORES detection | 476 |
| NORES associated | 324 |
| DFX testbed NOA detection | 288 |
| DFX testbed NOA associated | 227 |
| NDPC detection | 409 |
| NDPC associated | 302 |
| NDPC reviewed and associated | 259 |

For the associated detections, we have looked at azimuth residuals. The results in Fig. 7.3.1 demonstrate the improvement of the beamform $\mathrm{F} / \mathrm{K}$ process using new time delay corrections (upper right figure) as compared to the old beampacking technique (lower left). The automatic DFX process has azimuth residuals comparable to those of the analyst review detections at NDPC. It should be noted that further improvements may be achieved when the analyst at IDC can revise slowness estimates for any array. The NORES residuals are obtained from the REB NORES azimuths.

During the period analyzed, the NDPC analyst reported 9 additional events that were not in the REB. Four of these events were defined as origins on the testbed with NOA association.

It seems to be fair to draw the conclusion that DFX processing of NOA data is close to satisfactory. The most important improvement to concentrate on is to reduce the number of missed detections. The time delay corrections used seem to satisfy the expectation of smaller azimuth residuals for a larger array.

Before making any definite statement about missed detections, it is necessary to gain further experience with analyst review. This would involve looking at optimum beams for NOA and verifying whether or not a detection should have been triggered.

For any event defined at the IDC, an array beam will be presented for the analyst. The process used to create this beam - Beamer - has not yet been modified to adopt time delay corrections. It is necessary for the analyst review to have this ability to make NOA beams. In the near future, the IDC plans to replace Beamer with DFX, and NORSAR staff will assist in this process. When this has been completed, NORSAR processing can be implemented as part of regular IDC operation.

Fig. 7.3.1. Distribution of azimuth residual for associated detections. The residual is the absolute value of the difference between predicted and observed backazimuth for events where the detection was associated according to the criteria in the text. The upper left shows distribution for the NORES associated detections. The upper right shows azimuth residuals for DFX NOA detections. The lower left shows residuals for automatic NORSAR prcoessing using old beampacking and old time delay corrections. The lower right figure shows residuals for NORSAR detections refined by analyst review at NDPC. (Old time delay corrections).

### 7.4 Threshold Magnitudes

## Introduction

This note is intended to explain some of the basic principles and assumptions behind the calculation of threshold magnitudes, such that the reader can get an understanding of how this method can be used as part of a CTBT verification system. In addition, we will outline the current status on the development of the threshold monitoring system, as well as the plans for further improvements and extensions.

## Definition of station and network magnitude thresholds

Several studies have confirmed that global observations of body-wave magnitude $\mathrm{m}_{\mathrm{b}}$ are normally distributed with a standard deviation of about $0.4 \mathrm{~m}_{\mathrm{b}}$ units (a.o., Veith and Clawson, 1972; Ringdal, 1976). This is one of the basic assumptions behind the calculation of $\mathrm{m}_{\mathrm{b}}$ magnitude thresholds.

If we look for a hypothetical event at a given location and origin time, and consider a "noise situation" at a given station $i$, i.e., that there are no phase detections at the predicted phase arrival time of the hypothetical event, we can calculate a so-called "noise magnitude" $a_{i}$.

If a hypothetical event of magnitude $m$ really was present, it would have phase magnitudes $m_{i}$ normally distributed around m , and for station $i$ we would know that $m_{i} \leq a_{i}$. This is used in the statistical derivation of the single station and network magnitude thresholds, and for details we refer to Ringdal and Kværna (1989, 1992).

Using the formulas developed for calculation of network magnitude thresholds we find that if we e.g., have one single station observation with a "noise magnitude" of $m_{b} 4.0$ for a hypothetical event at a given location and origin time, we can say (with 90 per cent confidence) that a hypothetical event would need to have an $m_{b}$ less than 4.52 . If we, on the other hand, had two station observations each with a "noise magnitude" of $m_{b} 4.0$, we can say (with 90 per cent confidence) that a hypothetical event would need to have an $m_{\mathfrak{b}}$ less than 4.20 . In a similar way, all network station observations of "noise magnitude" can be combined to place an upper $\mathrm{m}_{b}$ limit on a hypothetical event occurring at a given location and origin time.

By repeating the calculation of network magnitude thresholds in origin time steps, we obtain a so-called threshold trace for a given geographical location. It has been shown in several NORSAR reports and papers that such a threshold trace can be effectively used to conduct a sitespecific threshold monitoring of interesting areas like the Novaya Zemlya and Lop Nor nuclear test sites.

By gridding the Earth into discrete target areas, we can compute threshold traces for each separate target area, and then interpolate to create global or regional maps of magnitude thresholds. From inspecting these maps we can get an instant picture of the monitoring capability of the network, as well as being able to identify regions and time intervals with particularly high magnitude thresholds. The primary causes of such increases would be signals and coda from large events and/or station outages.

## What happens to the magnitude thresholds when an event occurs?

In cases when signals are observed from an event occurring in the target area, we would for the detecting stations have $m_{i}=a_{i}$ and not $m_{i} \leq a_{i}$, which was one of the basic assumptions behind the statistics of the network threshold calculations. In such a case our magnitude threshold will be biased low, and the bias will generally increase with the magnitude of the event. In such a situation, the correct approach would be to use the maximum-likelihood formalism of Ringdal (1976), taking into account both the detecting and non-detecting stations of the network. But this will require that we have available both the event locations from the standard network processing, as well as knowledge of which stations had detections on the beams used for threshold calculations.

As a preliminary solution to this problem, we have chosen to provide information on the detected events (from the AELs or the REBs) together with the threshold maps and threshold traces, such that the user can be aware that the actual threshold magnitudes are biased low around the origin time and location of the events.

Strictly speaking, the magnitude threshold calculations should also handle situations when an event occurred in the target area, without being detected by the processing algorithms. The reason for this could be SNRs below the detection thresholds or too few stations detecting the event. In this case the bias in threshold magnitudes will be negligible, and the conservativeness used in our parametrization should be able to accommodate such situations.

As an example, a 3 station event in Finland with a maximum-likelihood $m_{b}$ of 2.71 resulted in a $90 \%$ magnitude threshold of 2.66 using data from the full Alpha network. This event was, however, detected by the processing algorithms, so the difference between the estimated $\mathrm{m}_{\mathrm{b}}$ and the $90 \%$ magnitude threshold is probably higher that what can be expected for nondetected events. In any case, the bias effect resulting from ignoring the detection information is very small for such low-magnitude events.

## Tuning of the Alpha network

In order to obtain useful and reliable results from the Threshold Monitoring (TM) system, we have during the last months spent most of our resources on the tuning of the stations in the Alpha network. From analysis of a fairly extensive event database of 20-60 events per station, we have for each of the stations derived the following parameters:

- The frequency bands for filtering of the beams used to monitor targets in the different distance regimes (local, regional or teleseismic).
- The relations between the manual $\mathrm{A} / \mathrm{T}$ measurements in the $0.8-4.5 \mathrm{~Hz}$ band and the STA values of the filtered beams. This has been done to ensure compatibility between the PIDC magnitude measurements and the magnitude thresholds provided by the TM system.
- For the arrays, we have derived beam sets that ensure complete coverage of the entire Earth, using the constraint that the maximum allowable beamloss caused by mis-steering of the beams was 3 dB . In addition, we have derived expected values for the signal loss by beamforming.

The derivation of frequency bands for filtering of the beams was a quite difficult task, as it often involved balancing of two conflicting demands. The first was to ensure that for the events analyzed there was generally a good correspondence between the STA values of the filtered beams and the manual $\mathrm{A} / \mathrm{T}$ measurements in the $0.8-4.5 \mathrm{~Hz}$ band. On the other hand, we also wanted to obtain low magnitude thresholds during regular noise conditions.

In order to verify the quality of our tuning, we have for about 15 events compared the PIDC station magnitudes with the station magnitudes derived from the STA traces of the TM system. The agreement seems to be remarkably good, but because of the small data set available at NORSAR, we have not yet been able to compile any comprehensive statistics.

An example is given in Table 1, for an event located southwest of Africa. For all Alpha stations outside the distance interval 97-125 degrees, we have computed station magnitudes from the STA traces of the TM system. Except for the station LPAZ, we find a very close agreement between the PIDC station magnitudes and the STA magnitudes. We suspect that the PIDC station magnitude at LPAZ actually is a measurement of the strong noise field leaking into the 0.8 4.5 Hz filter band. The dominant period of 1.6 seconds indicates this. For LPAZ, we have in the teleseismic regime decided to use a bandpass filter between 1.0 and 4.5 Hz for calculation of STA station magnitudes. In this particular case, this filter ensured that we actually measured the signal. At the bottom of Table 1 we show a comparison between the PIDC network magnitude, the PIDC network magnitude of the Alpha stations within 97 degrees, the STA based network magnitude of the Alpha stations within 97 degrees, and the STA based network magnitude of all Alpha stations outside the distance interval 97-125 degrees. A significant feature is the lower standard deviation of the STA based station magnitudes.

The reason for not having analyzed a larger data set is that we need to transfer all raw data of the Alpha network to NORSAR prior to the analysis. But as soon as the new DFX beam recipes are operating on the Testbed, we would be able to compile such a statistics on a much larger data set. Our goal would then be to investigate whether the PIDC and the TM system provide on the average the same station and network magnitudes, and determine to which extent TM magnitudes are useful to supplement PIDC magnitudes.

## Network capability and magnitude thresholds

As another indirect test of the quality of the tuned TM parameters we have computed a simplified three-station detection capability map of the Alpha network using data from a time interval without any reported events. Our TM capability map has been computed by choosing the third lowest of the station "noise magnitudes", and then adding $0.7 \mathrm{~m}_{\mathrm{b}}$ units to accommodate an SNR of 5.0 required for phase detection. The TM capability for 1997-058:20.08 is shown in Fig. 7.4.1, where the black circles symbolize operating Alpha stations and the red circles symbolize Alpha stations without available data. This capability map show striking similarities with the simulated $90 \%$ detection threshold for the GSETT-3 network presented in Fig. 5.2.a of CD report no. 1423 (4 September 1996), although there are a few minor differences between the configurations of the GSETT-3 network and the operating Alpha network of February 27, 1997. Thus, the very simple "third lowest TM magnitude" approach provides an excellent approximation to the standard 3 -station $90 \%$ capability maps.

It should also be emphasized that the capability map of the GSETT-3 network is derived from statistical models of signal and noise characteristics, whereas the TM capability is derived from actually observed noise data. In this way, the TM approach is able to immediately accommodate variations in detection capability caused by "unusual" conditions like station outages, large earthquakes or aftershock sequences, which may cause the network capability to deteriorate for hours.

In contrast to the "capability maps" discussed above, the standard TM maps include no assumptions on the SNR threshold required for detection or the minimum number of stations required to generate an event hypothesis. Instead, the observed "seismic field" is used to place an upper limit to the magnitude of possibly hidden events. Fig. 7.4 .2 shows the $90 \%$ magnitude threshold for the same origin time instant as used in the capability map of Fig. 7.4.1. While the capability map of Fig. 7.4.1 tells us that for most of the region north of $30^{\circ} \mathrm{N}$ our processing algorithms will be unable to detect events below $\mathrm{m}_{\mathrm{b}} 3.5$, the threshold map of Fig. 7.4.2 tells us that if there was an event in this region it would need to have a magnitude below 3.0. For the areas close to some of the stations, the magnitude thresholds are even below 2.5 .

In somewhat simplified terms, we could say that the TM approach is able to "monitor" an area at an $\mathrm{m}_{\mathrm{b}}$ level 0.5 units lower than the conventional "detection based" approach.

In order to illustrate the effect of the occurrence of a large earthquake, we have estimated the three-station detection capability and the magnitude thresholds for a time instant 9 minutes after the origin time of a $\mathrm{M}_{\mathrm{S}} 7.2$ earthquake located in Pakistan. The capability map of Fig. 7.4.3 tells us that except for parts of Australia and parts of north and south America, the detection threshold is above 4.5 for the entire Earth. For parts of Asia and Africa, the threshold even exceeds 5.0.

When turning to the magnitude thresholds of Fig. 7.4.4, we find significantly smaller numbers. The usefulness of the threshold map is illustrated by the fact that while we could not be certain to detect a magnitude 5 event in parts of Asia and Africa, the threshold map tells us that a hypothetical event in these regions could not have had a magnitude significantly above 4. For most parts of the world, we find the upper magnitude limits to be about $1 m_{b}$ unit lower than the three-station detection capability in this case. So the "gain" by applying the TM technique is even greater than during noise conditions.

## Usage of magnitude thresholds and capability maps in CTBT monitoring

It should be evident from the discussions above that both the magnitude threshold maps and the detection capability maps could be useful supplements in the monitoring of a CTBT. While the capability maps provide the lowest event magnitude the processing system is likely to detect, the magnitude threshold maps put an upper limit to the size of a possibly hidden event.

An application of the capability maps and the threshold maps would be to provide continuous confirmation and quantification of the monitoring capability of regions of interest to the international community. In addition, these maps would also provide an instantaneous warning and quantification of a reduced monitoring capability during station outages or high-noise intervals.

Another scenarios for the use of the results from the TM system would be investigation of time intervals for which questions have been raised regarding possible non-compliance with the treaty. By going back to the magnitude threshold maps for a given region and time interval, we could by selecting the pointwise maxima of the magnitude threshold maps for the given time period, get a useful overview of the maximum size of a hypothetical event in the region during this time period. This could be helpful to decide if further investigation would be needed. Along the same lines we could display the threshold trace for given target areas. If this trace shows an increase that is not caused by any known event, and at the same time exceed a magnitude threshold of interest, it might be meaningful to continue the investigation. E.g., our onemonth monitoring experiment of the Novaya Zemlya test site (Kværna, 1992) showed that from inspection of the threshold traces, we were able to exclude $99.7 \%$ of the total time from search for signals from possible events at the test site. The remaining $0.3 \%$ of the time contained threshold increases that could be explained by signals from detected interfering events.

If the magnitude thresholds for a given region show increased values during a particular time interval, we would like to know the reason why so happened. Signals from events located outside the region, station outages or increased noise levels at some stations are usually the main causes. By looking into the event bulletins and the station performance reports it should be possible to explain the majority of the threshold increases. But if threshold peaks remain unexplained, we should start to look more closely for events in the target region. This could be done by optimized manual data analysis of the stations known to have the best capability for the given target region, and/or by requesting and analyzing additional data.

## Status and plans for TM development for the PIDC

Our most immediate task for the TM development for the PIDC is to install the tuned processing recipes for the Alpha network on the Testbed. Following this installation it will be necessary to monitor the performance of the processing system both with regard to operational reliability, processing load and quality of the results. After this test is completed, hopefully within 3-4 weeks after the installation on the Testbed, we would be ready to consider the transfer of the TM processing system to the operational pipeline.

During the last months we have also been working with the development of TM products to be distributed from the PIDC. So far we have developed a program for creation of maps with pointwise maxima of the magnitude thresholds for each half-hour time interval. We will continue the discussions with the PIDC staff on which and how the TM products can be presented within the framework of PIDC services.

Another remaining task is the development of procedures for archiving of TM results. We have not yet decided how to do this, but it seems reasonable to store both the basic STA traces for each of the Alpha stations, as well as the maps provided through the PIDC services. But before deciding on the archiving procedures, we have to define the contexts in which the archived data are to be used. By contexts we mean situations like focused investigation of particular areas for previous time intervals, or re-assessment of the monitoring capability using additional data from the Beta stations or non-IMS networks.

We would also like to emphasize that we still consider the TM system to be experimental and under development, and that we have concentrated on producing high quality results from the basic processing algorithms. As soon as we have confirmed the quality of these computations, we will be ready to go ahead with the development of functions and products that can be useful for monitoring compliance with the CTBT. Our main focus will be on the usage of threshold and capability maps, as well as the threshold traces for each of the target areas.

## Future applications

For the future, we have in mind several interesting applications of data from the TM system that could be useful in the CTBT context.
E.g., we showed in the previous chapters that there seems to be a very good agreement between the PIDC magnitudes and the STA based magnitudes from the TM system. It would therefore be interesting to investigate if the usage of STA based magnitudes will provide any improvement to the network $m_{b}$ estimates. By combining the STA traces with a detector, it will also be quite straightforward to implement procedures for automatic maximum likelihood $\mathrm{m}_{\mathrm{b}}$ estimation, which again will help to reduce the $\mathrm{m}_{\mathrm{b}}$ bias problem for smaller events.

Another interesting application is threshold monitoring of surface waves. In principle, such processing should be feasible using the already existing processing modules, but some studies on filter settings, STA lengths and the usage of surface magnitude correction tables would be needed. The upper limit $\mathrm{M}_{\mathrm{s}}$ calculation could be applied to extend the functionality of discriminants like $\mathrm{M}_{\mathrm{s}} / \mathrm{m}_{\mathrm{b}}$. For small explosions, surface waves frequently are too weak to be observed at any station of the recording network. Obtaining reliable upper bound on $\mathrm{M}_{\mathrm{s}}$ in such cases would expand the range of usefulness of this discriminant. In practice, an "upper bound" for single station measurements has often been given as the "noise magnitude" at that station, i.e., the $M_{s}$ value that corresponds to the actually observed noise level at the expected time of the Rayleigh arrival. The threshold monitoring procedure will include this as a special case of a more general network formulation.

Once we have at hand reliable automatic procedures for both magnitude estimation and upper limit calculation of $m_{b}$ and $M_{s}$, it might provide useful to investigate the usage of these data for automatic event screening via $\mathrm{M}_{\mathrm{s}} / \mathrm{m}_{\mathrm{b}}$.

As a final comment, we still believe that the best monitoring performance is achieved through an optimized site-specific monitoring, incorporating region-specific calibration information like travel time, slowness and magnitude anomalies, and optimal bandpass filters for assessment of magnitude thresholds. Such high-quality monitoring has already been demonstrated for the Novaya Zemlya and the Lop Nor test sites, using data from the Scandinavian arrays. By integrating the output from the optimized site-specific threshold monitoring with the results from "traditiona" data analysis of detected signals we would utilize the resources of the monitoring network in a new tool that might enable a very high continuous automatic monitoring capability.

### 7.5 Study of seismic travel-time models for the Barents region

## Introduction

As part of a project aimed at improving seismic monitoring capabilities under a CTBT, NORSAR and Kola Regional Seismological Centre (KRSC) have begun a comprehensive study of seismicity, seismic wave propagation and seismic event location in the Barents region. This paper gives initial results from this research program.

As is well known, accurate location of seismic events with a regional network requires detailed knowledge of the propagation characteristics of seismic waves in the region. For Fennoscandia, an excellent velocity model (the NORSAR model) has previously been developed, and is being used at both KRSC and NORSAR.

An example of the importance of choosing the correct regional velocity model was given by Ringdal (1997) for the 13 January 1996 event near Novaya Zemlya. In the present study, we have applied the NORSAR model to the general Barents region, including Western Russia, and compared it with the IASPEI 91 model which is currently used by the GSETT-3 IDC. The purpose has been to investigate to which extent the NORSAR model is adequate for this entire region.

## The station network

The regional seismic network in the Kola Peninsula currently comprises 7 seismic stations, as described by Kremenetskaya et. al. (1995). For the present study, only those stations with digitally recording equipment have been used. In addition, several stations in Fennoscandia, some IRIS stations, as well as stations contributing to the GSETT-3 IDC have been used. We have only used data from stations within an epicentral distance of approximately 30 degrees for each event, and concentrated on station-epicenter combinations that cross parts of the Barents Region. The stations are listed in Table 7.5.1, and shown on Figure 7.5.1.

## Data base

We have selected six well-recorded events in the region, including the calibration explosion in Khibiny on 29 September 1996. For this one event the exact location and origin time is known, whereas for the other events we have recomputed the location using available stations in the GSETT-3 network, the Kola network and the IRIS network.

In order to minimize the effect of unknown velocity structure, we have used only P-readings in the relocation procedure. This method is less sensitive to regional variations than using a combination of P and S , because a shift in P -velocities will cause a shift in origin time, without influencing significantly the epicentral estimate. In fact, the IASPEI-91 model and the NORSAR model gives almost identical location estimates when using P-waves only. All the events are either near-surface (explosions) or shallow earthquakes, and the depths have been constrained to 0 in the location procedure.

The estimated locations, using the NORSAR P-wave travel time model, are given in Table 7.5.2. The paths from each recording station to the epicenter of each of the six events are shown
in Figure 7.5.2. It can be seen that the Barents sea is well covered, and some of the paths cover parts of Fennoscandia/NW Russia as well.

## Travel time analysis

After locating the events, we have compared predicted and actual $P$ and $S$-wave travel times, using both models. Our approach has been, for each model, to use the estimated epicenter and origin time based on the P-data for that model, and then compare the predicted and observed Sarrivals.

Figure 7.5 .3 shows the results for the IASPEI model. The P-wave fit is naturally good, because the $P$-waves have been used to determine the origin time and epicenter of each event. However, the observed S -wave velocities are consistently higher than those predicted by this model.

Figure 7.5 .4 shows corresponding results for the NORSAR model. The P-wave fit is again good for the same reason as outlined above. In addition, the $S$-wave data now shows excellent fit between the predicted and observed arrivals.

We conclude that the NORSAR model is appropriate not only for Fennoscandia, but for the entire Barents region from Spitsbergen to Novaya Zemlya, and also for northwestern Russia. Use of this model would be expected to improve location accuracy considerably compared to the use of IASPEI-91, especially when both $P$ and $S$ phases are used in the location procedure.

As an illustration of the difference between the two models, we will present an example, namely, the 13 June 1995 event near Novaya Zemlya. This is Event 5 in our data base, and has been discussed in detail by Ringdal (1996). Waveform plots and predicted phase arrivals for this event are shown in Figure 7.5 .5 (for the IASPEI model) and 7.5.6 (for the NORSAR model). For each figure, the predicted P -arrivals are consistent with the P -onsets. This is a consequence of using the P-arrivals for the respective models to estimate the location and origin time. We note, however, that while the theoretical S-wave arrivals are very accurate for the NORSAR model, they are far too late for the IASPEI model.

## Discussion

The first event was the calibration explosion on September 29, 1996, which has an accurately known location and origin time (Ringdal et al, 1996). We were therefore able to estimate accurate travel times and velocities for P and S . (see Table 7.5.3).

There are some interesting observations to be made from this table that will be subjected to further study. For example, the local velocity structure near Khibiny is highly azimuth-dependent, with low velocities to the north (Lovozero) and high velocities to the south (PLQ). This is also evident from the figures previously shown, which do not provide good fits to any of the two models at small distances.

Also, from Figure 7.5.3, the velocities across the western part of the Barents shelf appear to be even higher than those predicted by the NORSAR model. Admittedly, the difference is small compared to the difference between NORSAR and IASPEI, but it might still be a subject for further investigations.

Of special interest is to determine whether the NORSAR velocity model can be applied to improve the event locations made by the GSETT-3 IDC for the Barents Region. We have carried out a preliminary study, using a set of 52 Khibiny explosions detected and located by at least 4 stations (with P detections) in the GSETT-3 network. For each event, we compared the IDC locations (using the IASPEI model) with locations based on the same observations, but with the NORSAR model.

To obtain a simple measure of the results, we calculated the percentage of these 52 events that were located within 18 km of the true epicenter. It should be noted that a circular area of 18 km represents an area of approximately 1000 square km , which is a generally accepted target for location precision in the GSETT-3 network.

As it turned out, $21 \%$ of the IDC locations had errors of less than 18 km , whereas the number of such events was increased to $37 \%$ when using the NORSAR model for the same data. However, we observed that the S-residuals were rather large with the NORSAR model, and therefore attempted to locate the events using the P-phase data only (with the NORSAR model). This resulted in $62 \%$ of the events being located with an error of less than 18 km , which is a significant improvement over both of the other approaches (see Fig. 7.5.7).

It appears from this result that the S-phase readings used in the GSETT-3 bulletins might be less accurate than desirable. The reasons for this is unknown, but will be further investigated.

In the absence of a well-calibrated velocity model, it might seem preferable to make epicenter estimates based on P-phases only, since these location estimates are less sensitive to model errors than locations based on a combination of P and S phases. However, it must be noted that the S-phases, even in the absence of a good velocity model, do place important constraints on the distance to the epicenters. The use of $S$ therefore in many cases reduces the likelihood of gross error, which might occur if there are only few P-readings with poor azimuthal distribution. We plan to conduct more detailed studies of this problem in the future.

Figure 75.2: Station-event paths for the six seismic events used in this study. Only paths for which data has been available are shown.

Fig. 7.5.3: Theoretical and observed P-velocities (top) and S-velocities (bottom) using the IASPEI travel-time model. The event locations used for this figure have been made on basis of the $P$ wave data using the IASPEI model, and consequently the $P$-wave data fits the model well. However, the predicted $S$-wave velocities are consistently lower than the observed data, indicating that the IASPEI model is not suitable for the region studied.

Fig. 7.5.4: Theoretical and observed P-velocities (top) and S-velocities (bottom) using the NORSAR travel-time model. The event locations used for this figure have been made on basis of the $P$ wave data using the NORSAR model, and consequently the $P$-wave data fits the model well. In addition, as opposed to Fig. 7.5.3, the predicted S-wave velocities are in quite good correspondence with the observed data, indicating that the NORSAR model is well suited for the region studied.

Fig. 7.5.5 Illustration of the predicted P and S phases for the IASPEI model for event 5 in the data base. The predicted time difference between $P$ and $S$ (vertical bars) clearly do not match the observed onsets.

Fig. 7.5.6 Illustration of the predicted P and S phases for the NORSAR model for event 5 in the data base. In contrast to Fig. 7.5.5, the predicted time of arrival of $P$ and $S$ (vertical bars) match the observed onsets quite well.

## Location error - Khibiny

Fig. 7.5.7 Histograms showing the distribution of location errors for 52 Khibiny mining explosions: a) IDC locations (using $P$ and $S$ data with IASPEI model), b) Locations using IDC data ( $P$ and S) but with NORSAR model and c) Locations using $P$ data only. Note that case c) shows less error for the majority of events, although there are some outliers.
